instantaneous axis of rotation precesses. Stresses and magneto-hydrodynamic waves are therefore to be expected at the surface of such a star³. This will dissipate energy with the final result of bringing the system into an equilibrium state, that is, the magnetic axis in coincidence with the axis of rotation. Acceleration of particles to relativistic energies is to be expected under these circumstances.

The same picture of an oblique rotator leads also to a different possibility, that is, that the neutron star might directly emit electromagnetic waves of very low frequency (in the kc/s range). This idea has been suggested by Hoyle, Narlikar and Wheeler⁴ as a possible consequence of the vibrations of a magnetic neutron star. Because the rapid damping of the vibrations makes it difficult to retain this suggestion in the original form, I wish to point out that the oblique rotator model also results into an analogous emission of electromagnetic waves.

If d_0 is the projection of the dipolar moment on the plane perpendicular to the axis of rotation and Ω is the angular velocity of the star, there will be a monochromatic emission of electromagnetic waves at the frequency $\omega = \Omega$. The corresponding intensity is given

$$I = \frac{2}{3} \frac{d_{6}^{2} \Omega^{4}}{c^{3}} \tag{2}$$

If we take d_0 to be about $H_0R^3 = 10^{10} \times 10^{18}$ gauss cm² and $\Omega = 10^4$ sec⁻¹, the intensity would be of the order of 2×10^{40} ergs/sec.

We must, however, ask ourselves the question whether this radiation will ever arise. Any variation of the magnetic field can actually be compensated by the electric currents in the surrounding matter. Hoyle, Narlikar and Wheeler⁴ have stated that the strong gravitational field creates a near vacuum immediately outside the star so that in this region no propagation difficulty would arise. This equilibrium picture, however, seems unlikely for a newly formed neutron star, soon after the supernova explosion. It is then necessary to evaluate the maximum gas density which still allows the emission of electromagnetic waves. This is easily done if we note that the maximum current density in the gas is given by $j=n_eec$, where n_e is the electron density. The Maxwell equation

$$\operatorname{curl} \overrightarrow{H} = \frac{4\pi}{c} \overrightarrow{j} \tag{3}$$

gives then the maximum induced field. If we take $\operatorname{curl} \sim 1/r$ (r is a characteristic length of the order of the size of the system) we obtain

$$H_{\max} \sim 4\pi \, n_e \, e \, r \tag{4}$$

Any variation of the magnetic field of the order of the field itself cannot therefore be compensated by the induced currents if

$$n_e < \frac{H}{4\pi e r} \tag{5}$$

Assuming again H to be about 10^{10} gauss and r=R, about 10^6 cm, we must require $n_e<10^{13}$ cm⁻³. This limit is certainly not very stringent and condition (5) is likely to be violated only at the beginning, that is, soon after the birth of the neutron star.

Once the electromagnetic waves are emitted and propagate in the supernova remnant, they will be reflected by the circumstellar gas if the plasma frequency exceeds the radiation frequency. For $\omega=10^4~{\rm sec^{-1}}$ this happens if $n_e>2.5\times10^{-3}~{\rm cm^{-3}}$ which is now a very low figure. The electromagnetic waves would therefore be unable to reach us, but by this means a large amount of energy and momentum could be pumped from the neutron star into the supernova remnant. In particular, the radiation will give an outward momentum to the nebula by being reflected and therefore accelerate its expansion. As a matter of fact, there is observational evidence that the motion of the Crab Nebula has been accelerated after the

original explosion: if we divide the size of the nebula by its present expansion rate, we get too short a lifetime. From a quantitative point of view, no difficulty arises because of the large amount of energy which can be stored in the neutron star under the rotational and magnetic form. As suggested by Hoyle, Narlikar and Wheeler4, generation of high energy electrons can be expected in the region where the electromagnetic waves are reflected and cause a rapid compression of the nebular

It seems therefore that, when the oblique rotator model is realized, it can lead to a release of energy from the neutron star. It is, however, clear that the model is very idealized and requires further investigation. particular, it would be important to evaluate the emission of gravitational waves from the star. This will depend on the mass distribution in the star as influenced by the rotation and magnetic field and will determine the ability of the gravitational waves to carry out rotational energy and angular momentum from the star.

I thank Dr E. E. Salpeter, Dr E. Schatzman and Dr M. Simon for advice. Ionospheric Irregularities caused by Acoustic Waves

This communication presents some observational evidence for ionospheric irregularities being formed because of the propagation of acoustic waves. The acoustic waves themselves are believed to have been associated with an earthquake experienced at College, Alaska. During the past few years several studies have been devoted to the problem of the generation of acoustic and acoustic-gravity waves by an earthquake. Many of these studies followed in the wake of the Alaskan earthquake of 1964 (refs. 1-4). A number of travelling ionospheric disturbances were observed at different places after the earthquake and these disturbances are believed to be a manifestation of the propagating acoustic-gravity waves^{5,6}. Here we do not intend to explore the problem of the excitation of acoustic waves by an earthquake, and implicitly assume the existence of acoustic waves associated with an earthquake. This assumption seems to be justified in view of the earlier studies and also from our own observations.

The motion of the neutral component in a partially ionized gas affects the ionized components as well. The acoustic waves propagating in the ionosphere may therefore create perturbations in the ionization which can be detected by radio methods. A theory of the formation of ionospheric irregularities by acoustic waves was put forward by Whitehead, in an attempt to explain the origin of sporadic E in the equatorial regions. With certain modification, the theory is also applicable to the auroral EWe present here some results from a partial reflexion experiment which provide observational evidence in support of the theory.

The partial reflexion experiment conducted at College uses a frequency of 3 Me/s and is primarily intended for the study of horizontal motions in the lower ionosphere by the spaced receivers method. During most of the time, echoes from both D and E regions are present. For recording purposes the receivers are gated to accept only one of the echoes, and the outputs from the three receivers are recorded on a multichannel Sanborn recorder. On the morning of June 21, 1967, rapid periodic fading, with periods from less than 0.5 sec to 2 sec, was observed in the wake of an earthquake felt at College. The earthquake occurred in a series of four shocks between 0804 and 0825 A.S.T. The equipment was switched on just after the second shock, which was felt at about 0814 h. The first indication of the disturbance in the reflecting region of the ionosphere was noticed at about 0819 h. Before this the signal was quite steady. The receivers were gated for the E region echo with its peak at 105 km. The signals recorded after the onset of the disturbance are shown in Figs. 1 and 2. The fading patterns in all the receivers are identical. The fading starts with a period of about 1 sec; the period as well as the depth of fading increases with time. After about 15 sec, a more rapid

Fading pattern of the E region echo (105 km) received at College soon after the earthquake on June 21, 1967.

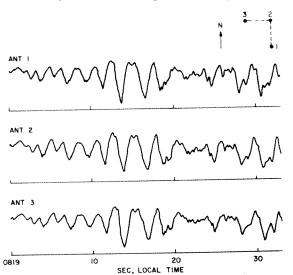

Fig. 2. Simultaneous recording of the signal in three spaced receivers. The north-south and east-west spacing between the antennas is one wavelength,

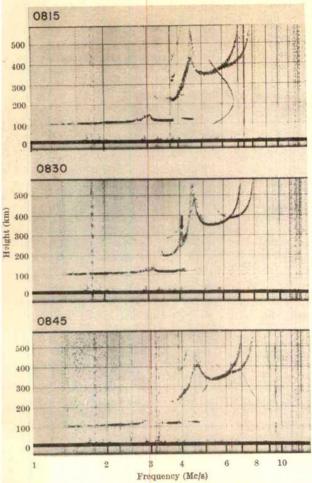

Fig. 3. College ionograms for 0815, 0830 and 0845 A.S.T. on June 21, 1967.

fading with a period of about 0.5 sec appears superimposed on the longer period variations. These short period variations last for 15 sec, after which only the long period fading remains. After another 15 sec, short period variations with a period of 1 sec appear; the period and the amplitude again increase with time. This sequence amplitude again increase with time. appears to be repeated and the signal level gradually Thus the disturbance seems to have arrived at the reflecting region in a series of pulses. The fact that the ionosphere was disturbed by the earthquake is also borne out in the regular ionosonde observations at College. Fig. 3 shows the ionograms taken at 0815, 0830 and 0845 h; the 0830 h ionogram shows an additional cusp at about 300 km which is not noticed in the earlier or later observa-

The rapid periodic fading of the reflected signal is not unusual. The regular sequence of increasing period, however, has not been observed on any other occasion during 1 yr of operation of the equipment. The association of these observations with the earthquake is immediately suggested. The time lag between the second shock and the observed fading is about 5 min. This roughly corresponds to a speed of propagation of about 350 m/sec, which is quite close to the acoustic speed. The 0830 h ionogram also agrees with the assumption that the disturbance propagated from below at the acoustic speed.

In view of the very short periods, the fading cannot be caused by periodic variations in the electron density at the reflecting level, for the relaxation period for the ionosphere at this level is much longer. Because the experiment uses vertical incidence, the fading is attributed to Doppler shift caused by vertical motions in the scat-

tering (or reflecting) region. The vertical motion must be in the range of 25-100 m/sec in order to give the observed Doppler fading. This motion cannot possibly be the physical motion of the medium itself. Vertical motions of the medium may be caused by oscillations of the ionospheric layer. These oscillations can result from acoustic gravity waves. The period of these waves has a lower limit which is of the order of a few minutes, while the periods encountered in the present observations are in seconds.

Because the observations are believed to be associated with the earthquake, it appears more reasonable to look for an explanation in terms of acoustic waves. acoustic waves propagating through the reflecting region will generate electron density irregularities which will be moving with the phase speed of the waves. The irregularities will be more intense for waves propagating at low angles to the horizontal and beyond some critical angle they will not be noticeable. Thus the observed fading can be produced by acoustic waves propagating at angles below the critical angle. The waves propagating with higher angles (within this range of angles) arrive first and cause the shorter period fading; these are followed by the waves propagating at progressively lower angles. This accounts for the gradual increase in the fading period. The increase in the fading amplitude is then accounted for by the fact that the irregularities are more intense for lower angle waves. According to this viewpoint, then, the vertical motion causing the Doppler shift is the vertical component of the wave velocity. A comparison of the fading pattern at the three antennas also gives confirmatory results. The horizontal motion is towards the north with a speed of 300-350 m/sec. Also the horizontal speed is less for the shorter period fadings which imply a larger vertical component. The periodic repetition of this sequence is in all probability caused by the pulsed nature of the acoustic wave excitation.

The role of the ionospheric irregularities in this case is different from their role in VHF scattering. relatively low frequency used here (3 Mc/s), the aspect sensitivity of these irregularities does not play a crucial part. The irregularities are not essential for obtaining the scattered signal; they act only as a perturbation on the existing mechanism of partial reflexion.

Terrestrial Origin of Aluminium-26 and Oceanic Sedimentation Rate

The recent detection of aluminium-26 in marine sediments by Amin, Kharkar and Lal¹ has posed a question about the origin of this nuclide. Lal and Venkatavaradan2 pointed out that the amount of aluminium-26 in sediments is an order of magnitude higher than expected, as a result of its production by cosmic ray interactions in the terrestrial environment. Thus they concluded that the large amount of aluminium-26 can only be explained by postulating an influx with extraterrestrial cosmic dust which

has been exposed to a significant flux of energetic particles

capable of producing nuclear interactions.

I have recalculated the figures of Lal and Venkatavaradan in the light of new cross-section measurements carried out by Yiou et al. (ref. 3 and private communication), and I have obtained a result which suggests that the large amount of aluminium-26 can be explained by its production through cosmic interactions in the terrestrial atmosphere.

Lal et al. found that the mean ratio of activity of aluminium-26 to beryllium-10 in a South Pacific core (0-110 cm deep) and a North Pacific core (0-120 cm) was 0.12 ± 0.04 , but the mean ratio in the cores 1 m deep is not very significant because the rates of decay of these nuclides are very different (Fig. 1). I have therefore used the measurements of beryllium-10 and aluminium-26 activities in the surface layer of the South Pacific core^{1,2}— 4.7 ± 0.5 and 0.78 ± 0.34 d.p.m./kg of dry sediment, respectively. Thus the ratio is 0.17 ± 0.08 and, after correcting for decay, the ratio of aluminium-26 to beryllium-10 in freshly deposited sediment is 0.2 ± 0.1 .

Lal and Peters⁴, however, estimated the global production rates of beryllium-10 and aluminium-26, by spallation of atmospheric nuclei, to be 4.5×10^{-2} and 1.4×10^{-4} atoms cm⁻² sec⁻¹, respectively, and these correspond to an activity of 7.5×10^{-7} and 7.9×10^{-9} d.p.m. cm⁻² yr⁻¹, respectively. Thus in a freshly deposited sediment, the activity ratio of aluminium-26 to beryllium-10 should be about 0.01. From this expected ratio, Lal et al. concluded that the observed ratio of aluminium-26 to beryllium-10 (about 0.1 or 0.2) is an order of magnitude higher than the expected ratio (about 0.01) and that most of the aluminium-26 may have an extraterrestrial origin.

Lal and Peters estimated rates of production based on the formation cross-section of beryllium determined by Honda and Lal⁵. Recent measurements, however, made by Yiou et al.3 with an elaborated method using a mass-spectrometer, have shown that the formation

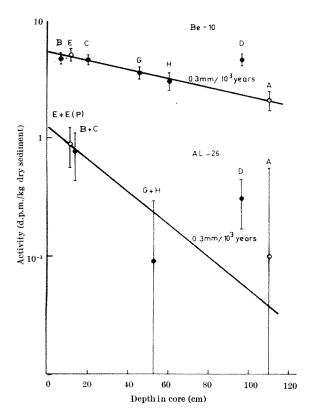

Fig. 1. The activity of beryllium-10 and aluminium-26 as a function of depth in oceanic sediments; ♠, South Pacific core (57° 35′ S., 174° 15′ W., 4,760 m); ○, North Pacific core (8° 20′ N., 145° 24′ W., 5,110 m).

Table 1. FORMATION CROSS-SECTION OF BERYLLIUM-10 Target \mathbf{C} CN₃O Cross-section (mb.) Honda and Lal (Ep., 220 MeV) Yiou et al. (Ep., 155 MeV) $^{1.8}_{0.3}\!\pm\!0.6$ 4 ± 2

0.4 + 0.2* * The formation cross-sections at E_P (proton energy) = 600 MeV and 19 BeV are about 0.6 ± 0.4 mb.

cross-section of beryllium-10 is an order of magnitude lower than the value obtained by Honda and Lal (Table 1).

Although the formation cross-section from nitrogen has not yet been measured, Yiou et al. tell me that it can safely be estimated to be of the same order as the cross-section from oxygen, using a systematic prediction. The low value of the new cross-section is consistent with an empirical rule on the systematics of spallation crosssections of light elements, proposed by Reeves: the cross-sections of the reactions which produce a nuclide having an isobaric spin of 1 (such as beryllium-10) from a nuclide having an isobaric spin of 0 (such as nitrogen-14 and oxygen-16) are, in general, an order of magnitude lower than the cross-sections of the reactions which produce a nuclide having an isobaric spin of 0 or 1/2 (for example, beryllium-7) from the same target.

The global production rate of beryllium-10 by spallation of atmospheric nuclei should therefore be an order of magnitude lower than the value expected by Lal and Peters. Thus, in a freshly deposited sediment, the activity ratio of aluminium-26 to beryllium-10 is expected to be about 0.1. An uncertainty factor of 2 may be involved in this expected ratio, because the formation cross-section of aluminium-26 is not actually measured but evaluated

from the semi-empirical rule of Rudstam.

This expected value agrees with the observed ratio, 0.2 ± 0.1 , within the experimental errors. Thus we can conclude that most of the aluminium-26 activity, found in marine sediments, can be explained by its formation from the spallation reactions in the terrestrial atmosphere, and we need no influx with cosmic dust.

Because of a slight excess of the observed ratio over the expected ratio, some cosmic dust contribution to the aluminium-26 cannot be excluded, but the uncertainty factor does not justify it. It would therefore be desirable to determine the formation cross-sections (particularly of aluminium-26) and the activity in sediments with more precision in future experiments.

Recent experiments of Nilsson⁷ suggest that previous estimates of the accretion rate of cosmic dust on the Earth may be exaggerated, for he has found that the counting rates of microphonic dust counters probably resulted from noise, provoked by temperature gradients rather than from the impact of micrometeoroids. influx rate of aluminium-26 with cosmic dust may therefore be considerably lower than the value estimated by Lal.

Apart from the origin of aluminium-26, and because of its revised cross-section, I have re-evaluated the rate of sedimentation by the beryllium-10 method. The aluminium-26 method was also used. This evaluation was carried out in two ways. (a) The production of beryllium-10 or aluminium-26 (in d.p.m./cm² yr⁻¹) was divided by the volume concentration of beryllium-10 or aluminium-26 (in d.p.m./cm3) in the freshly deposited sediments to obtain the sedimentation rate (cm/yr). The density of the core material, defined as the ratio of the dry weight of the core to the volume occupied by it in situ at the ocean floor, is about 0.5. This value was used to convert weight concentrations (d.p.m./kg) to volume concentrations (d.p.m./l.). Thus, from the data of beryllium-10, we found a value of about 0.3 mm/1,000 yr both in the South Pacific core and in the North Pacific core. The previous value by Lal was about 4 mm/1,000 yr.

From the aluminium-26 data, the sedimentation rate was found to be about 0.2 mm/1,000 yr. This rate agrees with the beryllium-10 rate, for it is within the experimental errors. These rates should be considered as the sedimentation rate of the surface layer.

(b) In the second evaluation of the rate of sedimentation the decay of beryllium-10 (aluminium-26) was plotted as a function of the core depths (Fig. 1). A regular decrease in the activities with the depth was found except in the fraction D (83-110 cm depth) of the South Pacific core. In fraction D, both the beryllium-10 content and the aluminium-26 content were exceedingly high. Although the reason for this irregularity of the fraction D is not known, we have eliminated temporarily the data of the fraction D.

The rate of sedimentation is obtained from the gradient of the decay curves. We found a rate of about 0.3 mm/ 1,000 yr from the decay of beryllium-10, which should be considered to be the mean rate of sedimentation between cores 0 and 1 m deep. Good agreement was found between this rate and the sedimentation rates of the surface layer determined by method (a). This means that there has been a constant sedimentation rate in these cores, and a constant cosmic ray intensity during the last 3×10^8 yr, with the reservation of fraction D.

The activity of aluminium-26 in each fraction was recalculated from the data of Amin et al.1. Because of the large statistical errors involved in measuring the rate of counting, it was not possible to determine the gradient of the decay curve, but a sedimentation rate of 0.3 mm/ 1,000 yr seems to be consistent with the decay curve. The decrease of the aluminium-26 to beryllium-10 ratio with depth was also consistent with this rate of sedimentation. All values from the beryllium-10 and aluminium-26 methods therefore indicate a sedimentation rate of about 0.3 mm/1,000 yr for these two cores. This rate may have an uncertainty factor of 2, because of the experimental errors in measurements of the cross-sections and the activities.

These figures obtained from the beryllium-10 and aluminium-26 methods agree well with the sedimentation rates, determined by Goldberg and Koides with the ionium to thorium ratio method, of 0.3 to 0.6 mm/1,000 yr in South Pacific cores.

Although discrepancy has sometimes been reported between the results by the ionium to thorium ratio method and those obtained by the protoactinium and carbon-14 methods, recent studies, have indicated the ionium to thorium ratio method or the ionium method with the protoactinium method are consistent. On the other hand, the carbon-14 method is not adequate to determine the very low sedimentation rate, because of its short halflife. We can therefore consider the low (about 0.4 mm/ 1,000 yr) sedimentation rate of the South Pacific Ocean as a well established fact.

The agreement of the sedimentation rates, measured by the beryllium-10 method and the aluminium-26 method, with the rates by the ionium to thorium ratio method indicates the usefulness of the former two methods in the measurements of the sedimentation rates and also the time variation of cosmic rays over the past few million years.

I thank Dr J. Labeyrie for his helpful discussions and also Professor R. Bernas and his group for use of their data before publication.

Emission of BO₂ from Injection of Triethylborane into the **Upper Atmosphere**

Hoffman, Palmer and Smith¹ recently presented a low resolution emission spectrum obtained from the sunlit release of triethylborane at a height of between 90 km and 178 km above the Earth. They assigned the observed bands to an $A^2\Pi^{-2}\Pi$ transition of boron oxide, even though they noted the absence of a band expected at 6025 Å on the basis of this assignment. Their communication does not make clear which oxide of boron is

assigned as responsible for the emission.

I believe the observed emission spectrum is that of the boric oxide fluctuation bands—a spectral system arising from a transition of the BO₂ radicals. A comparison is given in Table 1 between the wavelengths of maximum emission observed in ref. 1 and those reported in absorption for flames containing boron3. The correspondence between these data is as good as can be expected when a complicated spectrum of many lines is observed at low resolution. The 6025 Å band shown in ref. 4 and mentioned by Hoffman et al. is not a part of the BO₂ A² II-X2∏ system; therefore its absence in the upper atmosphere emission supports this assignment rather than presenting a difficulty.

> Table 1 Emission maxima from upper atmosphere release 1 Absorption maxima for 1 BO $_{2}$ in flames 8 6,4206,200 5,795 5,465

The boric oxide fluctuation bands were erroneously assigned to B₂O₃ for many years^{5,6}. The correct assignment of the spectrum to the BO2 radical was made independently in Russia⁷ and in the United States⁸ on the basis of spectral and chemical kinetic studies. This assignment was confirmed when this electronic spectrum was resolved, analysed and the molecular constants of BO2 determined. The key to success in this work lay in production of the emitter with a low rotational temperature by flash photolysis of boron trichloride-oxygen mixtures at low pressures. Those conditions are strikingly similar to those which obtained in the upper atmosphere release of Hoffman et al. Both experiments probably involve non-thermal excitation processes which obviate the use of the relative band intensities for thermometry.

In spite of its recent discovery, the properties of the BO_2 molecule are now well known. This is partly a result of the fact that its electronic spectrum is one of the best examples of the Renner effect. The thermodynamic properties of BO₂ have been computed¹⁹ and its heat of formation determined11. It may therefore usefully serve as a chemical probe for species with which it reacts in the upper atmosphere.

Hydrothermal Melting Curves in Silicate-Water Systems at Pressures greater than 10 Kilobars

Fusion curves, or melting intervals, for many elements, minerals and rocks have now been measured experi-

mentally to high pressures, but most determinations of melting relationships in the presence of water vapour have been limited to pressures below 10 kbar. It is well known that the solubility of water vapour under pressure in silicate liquids produces a marked depression of melting temperatures, as illustrated by the negative slopes, dP/dT, of the univariant curves for the reactions: albite+vapour= liquid (Fig. 1); albite + nepheline + vapour = liquid (Fig. 2). Barth1, Smith2 and Kadik and Khitarov³ have predicted that, because of the progressive change in the relative properties of water in vapour and liquid phases with increasing pressure, the slopes, dP/dT, of hydrothermal melting curves in silicate-water systems (solid-liquid-vapour) should change from negative to positive at moderate pressures, probably within the interval 3 kbar-10 kbar, with the curves passing through a temperature minimum where dT/dP = 0. We have recently extended water saturated univariant melting curves in the system $NaAlSiO_4$ - SiO_2 - H_2O from 10 to 35 kbar, using piston-cylinder apparatus, and none of the curves exhibited a temperature minimum where dT/dP = 0. Figs. 1 and 2 show some of our results. These are not complete phase diagrams; they show only the reactions en-

countered by two composition joins through the ternary system. Further reactions required by the existence of invariant points, I, and a singular point, S_5 , will be

illustrated elsewhere.

The reactions for mixtures on the composition join

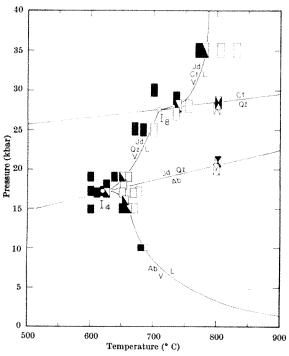

Fig. 1. Univariant reactions in the system NaAlSiO₄-SiO₂-H₂O encountered by mixtures on the composition join NaAlSi₂O₃-H₂O. The inflexion on the curve for Ab+V=L where this approaches the invariant point I_4 involves a change to the reaction Ab+V=Jd+L, which is not labelled. Abbreviations: Ab, albite; Jd, jadeite; Qz, quartz; Ct, coesite; L, liquid; V, vapour (aqueous fluid phase).

NaAlSi₃O₈-H₂O are shown in Fig. 1. This join is effectively binary up to 17 kbar, where the curve for the hydrothermal melting of albite, with negative gradient, terminates at the invariant point I_4 as albite breaks down to jadeite and quartz. At pressures above I_4 , the composition join is ternary and mixtures are involved in the hydrothermal melting reaction jadeite + quartz + vapour = liquid, which

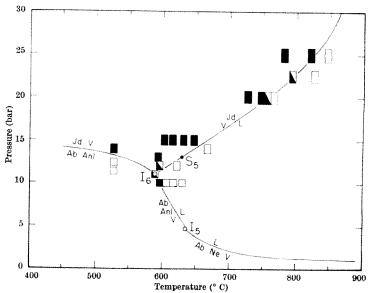

Fig. 2. Univariant reactions in the system NaAlSiO₄-SiO₆-H₂O encountered by mixtures on the composition join NaAlSi₂O₄-H₂O. I_5 and I_6 are invariant points, and S_5 is a singular point. Abbreviations as in Fig. 1, with Ne, nepheline, Anl, analcite.

has a positive slope. The melting curve crosses the quartz-coesite transition at invariant point $I_{\mathfrak{s}}$ with another marked change in slope.

The reactions for mixtures on the composition join $\operatorname{NaAlSi}_2\operatorname{O}_6-\operatorname{H}_2\operatorname{O}$ are shown in Fig. 2. The phase relationships are ternary up to the invariant point I_6 at 11 kbar, and effectively binary above it. The hydrothermal melting curve for jadeite, jadeite+vapour=liquid, extending above the invariant point I_6 , has a positive slope (dP/dT), with dT/dP about 17 degrees C/kbar , which is similar to the gradient of fusion curves for many dry silicate minerals, but quite different from any previously put lished hydrothermal melting relationships. The familar pattern is illustrated by the curves below I_6 , where jadeite is unstable. Mixtures with compositions on the join $\operatorname{NaAlSi}_2\operatorname{O}_6-\operatorname{H}_2\operatorname{O}$ are involved at low pressures in the reaction albite+nepheline+vapour=liquid, which terminates at the invariant point I_6 where analcite becomes stable⁴ Between I_4 and I_6 is the curve for the reaction albite+analcite+vapour=liquid.

The results shown in Figs. 1 and 2 establish that the slopes of hydrothermal melting curves for silicates can change from negative to positive at high pressures, but the change is imposed, in this system, by phase transitions involving a large volume decrease, $-\Delta V$: albite = jadeite + quartz (Fig. 1); albite + nepheline = jadeite, which passes near I_6 in Fig. 2. The change is not produced by a progressive change in the properties of water in liquid and vapour phases. This does not preclude the possibility that a hydrothermal melting curve could pass smoothly through a temperature minimum where dT/dP = 0, in a system where the minerals do not undergo phase transitions until much higher pressures. At pressures above 15 kbar, we have found that the water content of the silicate liquids is of the order of 30 per cent by weight, and the aqueous vapour phase contains a high, but undetermined, proportion of dissolved solids; thus the physical properties of liquid and vapour phases become similar with increasing pressure.

These results indicate that temperatures at which silicate rocks in the presence of water begin to melt continue to decrease with increasing pressure through the thickness of the Earth's crust (equivalent to about 10 kbar pressure on average). Predictions that temperature minima occur on melting curves in this pressure range are not substantiated by experimental studies.

PHYSICS

Relationships between the Masses of Subatomic Particles*

Two recent publications^{1,2} have listed the most reliable experimental figures for the rest masses of the known subatomic particles, and it would appear that the changes in the individual masses of these particles can be explained very simply by postulating the ubiquitous existence of a small particle of mass equivalent to approximately 26 MeV. In this communication, I shall call this minute particle a "tamaid" (Welsh, tam-ed: "a small piece"). The neutral tamaid is given the symbol t^0 and by analogy with baryons, mesons, and so on, the possibility of the existence of t^\pm tamaids cannot be discounted.

One singular advantage in dealing generically with uncharged particles is that complicating factors which result from electromagnetic mass effects are probably either eliminated or considerably decreased^{3,4}. I shall show that the masses of the known, neutral subatomic particles can be calculated with considerable exactitude if it is assumed that each particle consists of a π^0 meson (134.97 MeV) associated with an integral number, n, of neutral tamaid particles of mass, $t^0 = 25.95$ MeV, that is

 $M = \text{mass of a subatomic particle} = 25.95 \ n + 134.97$ (1

The magic number n has typical quantum characteristics and adopts values $n = 0, 1, 2, 3, 4 \dots$ and so on.

Table I shows the numerical application of this simple equation and shows that the calculated values for the individual rest masses, expressed in MeV, agree quite well with the experimental figures.

Table 1 UNCHARGED PARTICLES Mass M (MeV) (experimental) Mass M (MeV) (calculated) Difference (MeV) Integer, Symbol Type (experimental)

There is some experimental evidence for the existence of a \times meson of rest mass equivalent to (731 ± 2) MeV (ref. 5). A value of n=23 gives a calculated mass of $\times = 731.05$ MeV.

It could therefore be argued that the neutron, N, consists of a π^0 meson, associated with thirty-one tamaids

of type t^o , either as a static conglomerate or having the minor masses rotating in individual orbits of quantum number n=0, 1, 2, 3 and so on, the outward centrifugal forces, $t^o V^2/R$, being balanced by equivalent inward forces produced by mass interactions. Gravitational forces are usually considered negligible in nuclear calculations, but they could become enormous if the electromagnetic shape of the atomic particles were such that they permitted the close approach of the centres of mass of the particles concerned. Even for charged particles, the distance between the centres of mass need not necessarily be associated with the distance between the centres of electrostatic charge.

When applying the tamaid theory to the structure of the positively or negatively charged subatomic particles, one cannot ignore the possibility of the existence of tamaids of t^{\pm} type which would probably have masses of the order of $t^0=25.95$ MeV. The existence of quantum numbers for hypercharge, isotopic spin, angular momentum and parity would also have to be considered. By analogy with equation (1), π^{\pm} mesons (139-577 MeV) could be assumed to form the nuclei of charged subatomic particles, the n factors remaining the same as those taken for the uncharged sister particles, that is

mass of charged subatomic particle= M=25.76 n+139.577

If M for the positive subatomic particles is plotted against n the slope of the line is slightly less as shown in equation (2). Table 2 shows the application of this equation to present experimental data.

	Table	2. POSITIV	TELY CH.	ARGED PARTICLES	
Symbol	n	M (obse	rved)	M (calculated)	Difference
π^+	0	139-58	±0-014	139.6	+0.02
K+	1.4	493.78	±0-17	500-3	十多古是
e+	24	758-3	± 2·8	757-9	0-4
K	29	891.7	± 0.7	886.7	-5.0
P	31	938-256	± 0.005	938-28	+0.02
Σ^{+}	41	1,189.53	±0.08	1,195-6	+61
Σ_{γ}	59	1,660		1,659-6	(1+4
$\Sigma_{\mathcal{B}}'$	63	1,767	± 4	1,762-6	-44

The calculated value for the Σ^+ baryon is slightly high but is near to the experimental value for $\Sigma^-=1,197\cdot3$ MeV. The chief percentage divergence occurs with the K⁺ meson which has a calculated mass of 500·2 MeV. It is interesting that on the basis of the much more complex quark theory, Zeldovitch and Sakhurov² have also recently calculated a value of M=500 for this particle. The quark has not yet been discovered, but it is believed to have a mass equivalent to about one-third a nuclear mass, that is, about 330 MeV (ref. 3). The data of Tables 1 and 2 appear to confirm that changes in the masses of subatomic particles occur in such a way that the different

tial $\frac{\mathrm{d}M}{\mathrm{d}n}$ is of the fairly constant order of 26 MeV where n is a member of an integral series. It is remarkable that no subatomic particles are known which fall into the range n=1 to n=13, but there may be some basic physical reason for this peculiarity. For a tamaid of rest mass equal to 25.95 MeV, the de Broglie wavelength is of the order of $\lambda=4.78\times10^{-12}$ cm, which may be large for existence within a subatomic particle. If the tamaids agglomerate within a subatomic particle. If the tamaids agglomerate and if one considers the wavelength associated with the upper (n=13) tamaid agglomerate, then λ falls to 3.68×10^{-13} cm, a more reasonable value.

It could be argued that nuclear structures n=1 to n=13 are "forbidden" for these relativistic reasons, but once n=13 has been passed, the tamaid agglomerates can link up with the π meson in the range n=14, 15, 16, etc., to give the known mesons and baryons. It may be purely coincidental that the tamaid agglomerate at the end of the forbidden range would have a mass of (13×25.95) MeV = 337.3 MeV, which is almost exactly the hypothetical mass of the quark. According to the present theory, this mass, in association with a tamaid, or other masses, could pass

^{*} A further contribution will appear in a forthcoming issue of Nature.

the "forbidden" barrier and exist in the nuclei of sub-

Note added in proof. The value for the tamaid mass developed in this paper refers to the bound state, there being insufficient data to assess the binding energy. Should this particle ever be detected experimentally, serious consideration would have to be given to its possible occurrence in the core structure of the muons (4 tamaids) and the π mesons (5 tamaids).

Growth of Single Crystals of Silver lodide in Silica Gel

The great solubility of silver iodide in concentrated potassium iodide solution and the rapid decrease of this solubility on dilution with water suggested that single crystals of silver iodide could be grown by a gel method1 similar to that used for growing crystals of cuprous chloride. Indeed, small silver iodide single crystals have been grown from solution by a dilution method. They appear as hexagonal prisms up to 20 mm in length and 2 mm in diameter or hexagonal pyramids up to 3 mm long and 1.5 mm across the base and take about 6-8 weeks to reach this size3. It seemed plausible that a combination of the two methods would yield larger and better crystals.

Gels were prepared from 7 ml. sodium silicate solution (244 g Na₂SiO₃·9H₂O+500 ml. water), 8 ml. 2 M potassium iodide and 15 ml. 2 M acetic acid. The gelling mixture was allowed to set in a 25 x 200 mm test tube at 45° C, and a solution made from 57 g silver iodide, 260 g potassium iodide and 250 ml. water was added carefully when the gel had set. This solution was allowed to diffuse into the gel for about a week, poured off and replaced by water. The temperature was kept at 45° C throughout the experiment. Hexagonal plates appeared within a few hours and grew to about 5 mm diameter. One side of these crystals was smooth, the other showed ridges along the diagonals between corners of the hexagon and along lines parallel to the sides of the hexagon, suggesting that growth occurs along only one direction of the c-axis.

Electron microprobe analysis confirmed the crystals to be silver iodide. No contaminating silicon from the gel was found (to an accuracy of a few p.p.m.), but potassium was found in quantities up to 6 per cent in certain regions of the crystals, chiefly along the valleys between the ridges.

Smaller hexagonal plates (about 3 mm) were obtained by a slightly different and shorter procedure. Gels were prepared as described, except that potassium iodide solution weaker than 2 M, or water, was used in making the gelling mixture. When the gel had set, addition of the silver iodide-potassium iodide solution resulted in the growth of these smaller crystals in the gel within a week.

A similar set of experiments at room temperature (about 23° C) gave different results. The gels were again made with water instead of potassium iodide solution. Crystals grew in the aqueous layer above the gel as well as in the gel. The crystals in the gel appeared as completely clear small pyramids and prisms (about 0.05 mm). The crystals in the aqueous layer were hexagonal pyramids,

5 mm in diameter and 5 mm high. They had good surfaces, but were translucent rather than transparent.

THE SOLID STATE

Growth of Sapphire Filaments from the Melt

WE wish to report the growth of continuous sapphire (a-Al2O3) filaments from the melt with diameters in the range 0.05-0.50 mm, at rates up to 150 mm/min. The growth process almost certainly takes place (at the tip of the advancing filament) below, rather than above, the melt surface. There is an obvious similarity between the process described here and the dendritic growth of germanium and silicon previously described by various authors1.

Crystal growth experiments were conducted in an apparatus similar to a Czochralski crystal puller, using RF coupled to a carbon susceptor to heat the melt in a molybdenum crucible. It has been reported2 that sapphire crystals grown from molybdenum crucibles have a slight grey cast but do not contain significant amounts of molybdenum. Our experience is somewhat similar, though the grown crystals show no visible departure from transparency.

Fig. 1 shows an almost classical dendrite produced by allowing a melt of aluminium oxide to solidify onto a mass of solid aluminium oxide immersed in it. Dendrites were observed to propagate rapidly along the surface of the melt when the RF power was switched off. Careful X-ray examination of dendrites, such as the one shown,

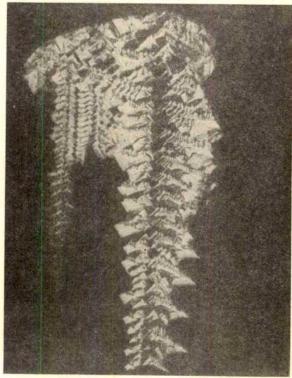

Fig. 1. Sapphire dendrite which grew in the c-direction (\times 40).

clearly demonstrates that most of the dendrites grow in the c-direction < 0001>. Other dendrites were found growing perpendicular to the very high index planes. Elongated dendrites growing straight downward were observed by rapidly pulling a mass of aluminium oxide from a rapidly cooling melt. These, too, were found to

be single crystals oriented in the c-direction.

Continuous c-direction growth of filaments has been achieved by properly controlling the thermal gradients in the melt. When the filaments are accurately oriented in the c-direction, the external surface is smooth, and they exhibit excellent mechanical properties. When the orientation departs slightly from the c-axis, the external surface of the filament reflects this in its morphology. This is demonstrated in Fig. 2, which shows four filaments (0.20-0.50 mm in diameter). Two are accurately aligned in the c-direction and two depart from it by small amounts, 9° and 11°. When the orientation departs even further from the c-direction, relatively gross jogging of the crystal occurs. The straight portions of the filament are inclined at an angle to the axis of growth but tend to grow in the c-direction. From the evidence presented, we conclude that the growth process is probably dendritic; and, because it does not require a particular twin geometry for its propagation, as is the case in germanium and silicon, the process may be described as auto-dendritic in the c-direction. Further demonstration of the dendritic nature of the process comes from an examination of filaments pulled rapidly from the melt. The tip morphology, under these circumstances, is strongly reminiscent of that reported for germanium dendrites1.

Mechanical measurement of the filaments at room temperature yielded a value for the average tensile strength of 300,000 lb./in.2, with high values of about 500,000 lb./ in.2 in filaments having diameters in the range 0·1-0·13 mm, as shown in Fig. 3. The modulus of elasticity was determined by a number of methods (including tension, bending, and ultrasonic propagation), yielding values ranging from 40-68 × 10⁶ lb./in.2. Because the filaments are single crystals, however, we believe that the modulus will approach the value characteristic of alpha alumina namely 67.5 × 106 lb./in.2, in the c-direction3. For comparison, similar strength measurements on centreless ground, flame polished, Verneuil grown single crystals have yielded tensile strengths in the range 72-102,000 1b./in.2, depending on orientation4. Sapphire whiskers, on the other hand, have exhibited tensile strengths in the range 1-2 million lb./in.2, but only where the diameter is very small⁵. For vapour-grown whiskers of diameters similar to those of our melt-grown filaments, values of 100,000 lb./in.² have been reported³. In brief, therefore,

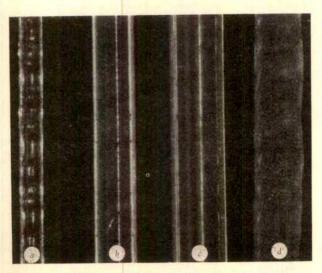

Fig. 2. Sapphire filaments which grew (a) 9° , (b) 0° , (c) 0° , (d) 11° to the c-axis (\times 30).

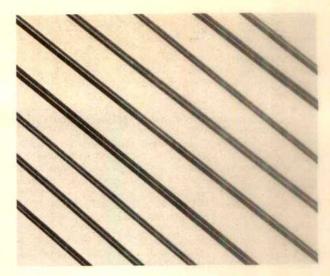

Fig. 3. Sapphire filaments 0·10-0·13 mm in diameter (×15).

the relatively massive filaments grown by our technique exhibit properties much closer to those of relatively perfect, very small whiskers than to those of larger diameter crystals obtained by another method.

In a more detailed account to be published later, the kinetics of the growth process are discussed and it is shown that very fast rates of growth may be possible, especially if forced convection is used to augment heat loss from the growing filaments. Because of the many potential technological uses for sapphire, it is interesting to note that we have already demonstrated multiple filament growth and the growth of continuous lengths of arbitrarily chosen cross sections. It is also clear that the process need not be limited to alumina but should be applicable to the growth of other materials which meet the basic crystallographic criteria for auto-dendritic growth.

We thank Dr Gunther A. Wolff, who has rendered invaluable assistance in X-ray crystallographic analysis, Dr George Hurley, who has provided much of the mechanical data, and Mr John Bailey, who has ably assisted in experimental phases of the programme.

Voids in Irradiated Stainless Steel

During development work on fuel elements for fast reactor applications, electron microscope examination by the thin foil technique has been carried out on samples of stainless steel irradiated in the Dounreay Fast Reactor, either in the form of cladding on experimental fuel elements or as specimens intended for mechanical property tests. The steel had a composition falling within the American Iron and Steel Institute type 316 specification as shown by the analysis given in Table 1.

Tabl 1. ANALYSIS OF STEEL IN WEIGHT PER CENT

A common feature of all specimens examined after irradiation to total neutron doses greater than 1022 n.cm⁻² in the temperature range 400°-610° C was the presence of spherical or polyhedral cavities ranging in size from the smallest observable to 1500 Å. Fig. 1 is an electron micrograph of one such specimen irradiated at 510° C to a total neutron dose of 4.7×10^{22} n.cm⁻².

Bubbles have been seen before in irradiated stainless steel1,2 and their origin has been ascribed to the segregation of helium generated by (n, α) reactions, involving boron-10 if the flux is chiefly thermal, but embracing all the components of the alloy when the incident neutrons have energies greater than about 3 MeV (ref. 3). In the present case, however, the void population is too great to derive solely from helium.

It has been demonstrated that the size of helium bubbles formed in metals in conditions of vacancy mobility is determined by equilibrium between surface tension and gas pressure. We can therefore estimate the apparent helium content of a specimen from bubble sizes and numbers, assuming that the gas pressure P in the bubble is $2 \gamma/r$, where γ is the surface energy and r is the bubble radius. The number of moles of gas, n, in a bubble is given by the Van der Waals formulae

$$P(V-nb) = nRT$$

where V is the bubble volume, b the Van der Waals constant, and T the temperature.

Application of this analysis to the present observations using a value for γ of 5,500 erg cm⁻² (ref. 5) gives a much greater quantity of helium than is known to be present, both from theoretical considerations³ and from gas analysis, the discrepancy in some cases being a factor of several hundred. For example, in the case of a typical fuel pin at the point where void volume was at its maximum, atomic fraction of the helium calculated from neutron flux and nuclear cross section data was 4.7×10^{-6} atoms per atom, while the fraction of helium deduced from the void population was 3.1×10^{-3} atoms per atom. The gas pressure within the voids must therefore be much less than that expected from surface tension considera-

The voids are thought to develop through the condensation of vacancies, which are generated prolifically during irradiation in a fast neutron flux, on the helium nuclei produced by (n, α) reactions.

This conclusion is supported by the behaviour of the voids on annealing. Specimens containing voids of average diameter 210 Å and occupying 1.5 per cent of the total volume were annealed for 1 h at 700° C and 900° C.

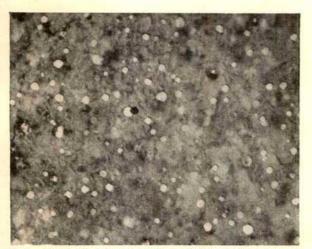

Fig. 1. Sample of fuel element cladding irradiated at 510° C to a neutron dose of 4.7×10^{22} ncm⁻² (\times 60,000).

	Table 2		
Total neutron dose $(n \times \text{cm}^{-2})$	Estimated mid wall can temp. (°C)	Average void diameter (Å)	Total void volume (per cent)
4·0×10 ¹²	270	_	
4.9 × 10 ¹¹	310	-	_
$5-3 \times 10^{22}$	380	_	-
5·2×10**	450	135	0.8
4·5×10 ²²	510	252	1.5
3·2×10**	560	258	0.2

While the 700° C treatment left the voids relatively unchanged, they were almost completely removed by the 900° C treatment, leaving a residue of porosity confined mostly to the grain boundaries and which could reasonably be equated with the helium content.

In typical irradiation experiments an axial temperature gradient is maintained in fuel pins which are exposed in flowing sodium, and one such pin was used to investigate the effect of irradiation temperature on void population. Specimens were taken at intervals of 3 in. along a 22 in. fuel element, the clad of which was originally in the solution treated condition, irradiated in the temperature range 270°-560° C. Average void diameters and estimated total void volumes are given in Table 2 together with irradiation temperatures and total neutron dose data.

Voids were seen only in the three hottest specimens, average void size increasing with irradiation temperature. The total void volume was peaked at 510° C.

The maximum void volume observed in any specimen so far examined was 7 per cent, this figure being confirmed by density measurement. The average void diameter in this sample was 1100 Å. This remarkable example of clad swelling occurred in a fuel pin at a point where the irradiation temperature was 500° C and the total neutron dose was 7.8×10^{22} n.cm⁻².

The cladding of this type of fuel element is subjected to considerable stress and strain during irradiation and there can be no doubt that these will influence void growth. Voids, however, have also been seen in unstressed material after irradiation, although the void fraction was smaller than in the samples from fuel pins. Thus it can be concluded that although stress may influence the subsequent enlargement of voids, it is not an essential prerequisite for void formation.

CHEMISTRY

Use of Ethylene as a Gas Phase Dosimeter for Accelerator Radiation

The radiolysis of ethylene has recently been extensively studied1-6 and the production of hydrogen has been increasingly used as a gas phase dosimeter, principally for irradiation with electrons and with gamma radiation. We have extended the previous dosimetry studies by measuring the yields of hydrogen from ethylene irradiated with about 1.5 MeV protons from a Van de Graaff accelerator and with 4.3 and 6.8 MeV helium ions from the Harwell Variable Energy Cyclotron, over a range of dose rates from about 6×10^{18} to 6×10^{20} eV g⁻¹ sec⁻¹.

Our need for a reliable gas phase dosimeter arose from the continuing use of all-silica irradiation vessels? in which the thin silica windows (2-3 mg/cm²) are distorted during fusion to their mountings. The most convenient method

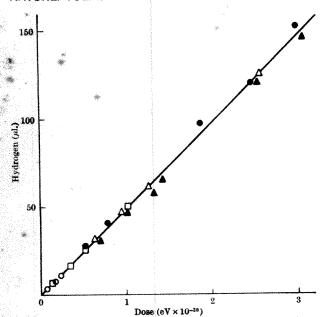

Fig. 1. Production of hydrogen from the radiolysis of ethylene. 1-5 MeV H⁺: \bigcirc , 5-75×10¹⁸ eV g⁻¹ sec⁻¹; \bigcirc , 5-75×10¹⁹ eV g⁻¹ sec⁻¹. 4-3 MeV He⁺: \bigcirc , 6-5×10¹⁹ eV g⁻¹ sec⁻¹. 6-8 MeV He⁺: \bigcirc , 4-1×10¹⁹ eV g⁻¹ sec⁻¹.

to estimate the loss of energy in the resulting non-uniform window is to measure the product yield from a gaseous dosimeter under the identical conditions used for subsequent irradiations of other gases. In order to establish reliable yields over the range of anticipated conditions, irradiations were carried out in a glass cell with a mica window of precisely known thickness cemented into place with 'Araldite' adhesive. The incident energies of the ion beams are known precisely and the energy losses in the mica window are calculated from range-energy datas and from the measured thickness of the window (2.69 mg/cm²). The geometry of the irradiation vessel is such that the ion beam is completely absorbed by the irradiated gas in a volume which is significantly less than the total volume Thus the insulated irradiated vessel corresponds to a Faraday cage and beam current measurements are made with a d.c. current integrator by inserting a platinum or tungsten electrode outside the irradiated volume in the vessel. The He+ ions lose an electron to form He²⁺ ions on passage through the mica window, but as the irradiation vessel is electrically earthed through the collector electrode the measured current corresponds to particles with only one positive charge.

Preliminary measurements with nitrous oxide over a range of dose rates were unsatisfactory principally because of the need to restrict doses to low values (<1020 eV/g) where the true initial yields can be measured. This requirement limited the irradiation times to a few seconds at the higher dose rates used, and while initial yields could be measured more accurately in a fast flow gas system this technique removes the elements of acceptable convenience and simplicity for a secondary dosimeter.

Measurements of the production of hydrogen from ethylene have, however, proved to be eminently satisfactory over a wide range of dose rates and of total dose. Ethylene from a cylinder (B.O.C.) was simply purified by two vacuum distillations at -78° C, collecting only the middle fraction (about 40 per cent) each time, and used without further treatment. The irradiations were carried out at ambient temperature and the radiolytic gases analysed by gas chromatography after passage through a liquid nitrogen trap; residual polymer on the walls of the cells had no effect on the yields, provided that the vessel was not opened to air between irradiations. The polymer could be removed eventually by treatment with chromic acid, or in the case of all-silica vessels by heating to 750° C with oxygen in situ. Irradiations were usually

carried out at a gas pressure of about 40 cm of mercury, but in one series of experiments with protons at a dose rate of about 2×10^{20} eV g⁻¹ sec⁻¹ the yield of hydrogen was unaffected by variations in gas pressure over the range 15-45 cm of mercury.

The experimental data are summarized in Fig. 1 for the two different ions (H+ and He+) from the two accelerators; only about 50 per cent of the data are included for clarity of presentation. It is clear that the production of hydrogen is a linear function of dose over the range of dose rates from about 6×10^{18} to 6×10^{20} eV/g and over the range of linear energy transfer for our experimental conditions—that is, from about $1.1 \times 10^{-3} \text{ eV}/\text{Å}$ (1.5 MeV H⁺) to about $7 \cdot 1 \times 10^{-3}$ eV/Å (4·3 MeV He³⁺) for ethylene at about 20° C and a pressure of about 40 cm of mercury. The slope of the line in Fig. 1 corresponds to an average yield of $G(H_2) = 1.31 \pm 0.02$

Perhaps the most striking feature illustrated by Fig. 1 is the linearity of the hydrogen yield up to high doset corresponding to ≤ 5 per cent decomposition. This results is probably unique to the irradiation conditions used because the polymer which is formed in high yields (G>11) settles onto the walls of the irradiation vessel and thus its concentration in the irradiated gas volume is always low and largely independent of dose. Even at 5 per cent decomposition the amount of radiation energy absorbed by the ethylene is only decreased by about I per cent as result of the accumulation of hydrogen and other gaseous products, under conditions where the ion beam still completely absorbed by the irradiated gas.

The measured yield agrees with values for other types of radiation at markedly different dose rates and values of linear energy transfer, namely

 $G(\mathbf{H}_2)$ Radiation 1·14 ± 0·28 (at 75 mm) 1·28 ± 0·19 (at 150 mm) (ref. 1) 1·2 (refs. 3 and 5) 1·2 (refs. 3 and 5) 2 MeV electrons 1 MeV electrons Gamma-radiation 1.2 ± 0.1 (ref. 6) 1.2 ± 0.1 (ref. 6)

Moreover, the independence of the yield with dose rate is in accord with previous evidence that the hydrogen is formed principally by a molecular detachment pro-These data demonstrate the usefulness of ethylene as a simple gas-phase dosimeter for work with accelerator beams and extend its increasing range of usefulness for dosimetry purposes in radiation chemistry.

Formation of Solid Free Radicals by Mechanical Action

THERE is a marked reduction of the molecular weight of nitrocellulose on pulping, for the length of fibres is considerably reduced in the process1.2. Staudinger et al.3 have found a similar effect when polystyrene, cellulose and nitrocellulose are ground in a colloid ball-mill, and have also found that nitrocellulose is partially denitrated when grinding is prolonged. These observations indicate that purely

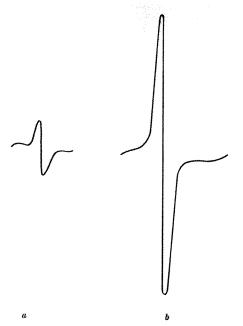

Fig. 1. a, Amber in grains 2–3 mm, amplitude 36 mm. b, Amber ground to $10-20\mu$, amplitude 170 mm.

mechanical cutting or breaking action can cleave covalent bonds.

I have now been able to show that free radicals are also formed by grinding solids. Materials, such as anthracene, acridine, cellulose and polyvinyl chloride powder, were ground in an agate mortar and free radicals were detected by electron spin resonance. An experiment with Baltic amber was particularly striking, for, after grinding a 0.0576 g sample of 2-3 mm diameter grains to $20-30\mu$, the intensity of the signal increased by 6.3 (Fig. 1a and b). The spectrum in Fig. 1a clearly indicates the existence of free radicals in the unground sample, confirming previous findings4. The intensity of the peak in Fig. 1a was calculated by taking Mn²⁺ in zinc sulphide (10¹⁵) as standard. The number of spins was 10¹³.

Although the intensity of the signal increased with grinding, it decreased with time and after a week was only 2.7 times its former, unground value. On further grinding the signal increased. Grinding once a week for three weeks to give a final diameter of 1-5µ gave about 10¹⁴ spins, ten times that of the original unground sample. Assuming that amber is a polyabietic acid, this led us to the figure 0.87×10^{-4} mol. per cent of abietic acid units in a free radical form.

Lagercrantz and Yhland⁴ have described how melted and solidified samples of calophony did not show the presence of free radicals, but grinding, however, gave an ESR signal, a finding with which our experiments agree. Powdered charcoal, $50-200\mu$ diameter grains, gave a strong signal-in agreement with previous findings with various types of coal⁵. Grinding the sample to 30-100u diameter grains gave in our experiments about an 18 per cent increase in the signal. The ESR measurements were carried out on an X-band apparatus having double modulation at 50 and 100 c/s.

I believe that the formation of free radicals by mechanical breaking and cutting, or scratching and polishing, could throw some light on phenomena, such as the charging of solids by friction6, and triboluminescence, which have not been fully explained. They both seem to result chiefly through a homolytic breaking of covalent bonds and formation of ions or radical-ions from free radicals. The charging of gases and liquids might also be explained on the basis of bond scission, the formation of free radicals and eventually ions or radical-ions, as a

result of thermal effects and a considerable increase of the temperature from the mechanical action.

The free radicals, caused by mechanical action, might lead to a reverse phenomenon by forming covalent bonds. This might explain the adhesion of polished surfaces in close contact; the "caking" of finely powdered substances (this would include powder metallurgy); the chemissorption of gases or liquids by solid adsorbants; and various phenomena associated with the beating of cellulose fibres^{7,8} such as an increase in the hygroscopic properties of cellulose pulp and an increase in strength of sheets made of cellulose.

Attention should also be given to the properties of charcoal as an ingredient in pyrotechnic compositions, such as gunpowder. Charcoal helps these mixtures to burn, and it is known that free radicals are essential intermediates in combustion and other chain reactions. The explosive nature of dusts, particularly coal dust, in air might be explained in terms of free radical reactions.

I thank Professor S. Malinowski and Dr S. Banbenek for examining the ESR spectra.

PHYSIOLOGY

Psychopharmacological Profile of Molindone

RECENT clinical reports1-3 have indicated that the combination of a neuroleptic and an antidepressant affords an added measure of therapeutic effectiveness in the treatment of certain mental disorders. In the course of our investigations on new psychoactive agents, we have found a compound (molindone hydrochloride, EN-1733A) with a profile in animals which predominantly resembles that of the neuroleptics and yet which contains some of the elements characteristic of antidepressants. eally, molindone (3 - ethyl - 6,7 - dihydro - 2 - methyl - 5morpholino - methylindol - 4 - (5H) - one) is unlike any of the psychotherapeutic drugs at present available.

When administered orally to rodents, dogs and monkeys, molindone induces phenothiazine-like behavioural changes. In mice (CF1 males) and rats (CFE females), molindone suppresses spontaneous locomotion, blocks a conditioned avoidance response and antagonizes stereotyped behaviour induced by amphetamine. Although less potent than chlorpromazine in mice, molindone is approximately two to three times more potent in rats (Table 1).

Table 1. RELATIVE POTENCIES OF MOLINDONE AND CHLORPROMAZINE IN RODENT NEUROLEPTIC TESTS

Test	Species	Relative potency (95 per cent confidence limits) molindone/chlorpromazine
Locomotor suppression*	Mouse Rat	$0.23 (0.13-0.46) \\ 2.97 (2.19-3.89)$
Avoidance blockade†	Mouse Rat	$0.17 \ (0.12-0.24) \ 1.78 \ (0.92-3.58)$
Amphetamine antagonism ‡	Mouse Rat	$0.31 \ (0.23-0.44)$ $2.38 \ (1.90-2.98)$

Determined during a 30 min period using four mice or one rat/photocell

Animals trained to avoid a shock by jumping to a ledge at the sound of a

buzzer.

† Intensity of sniffing, licking and biting estimated 1 h after subcutaneous injections into mice and rats of 12 and 6 mg/kg, respectively, of d-amphetamine sulphate.

Molindone was administered orally 1 h and chlorpromazine 2 h before each determination.

determination.

In mongrel dogs or beagles, 1-2 mg/kg of molindone causes a behavioural depression for about 3 h, characterized by decreased locomotion, miosis and reduced arousability. Higher doses intensify and prolong these effects and simultaneously induce such others as catalepsy, palpebral closure and, in some dogs, tremors or motor restlessness. In cats, the oral administration of 5-10 mg/kg is necessary to suppress motor activity and arousability and to cause miosis. Palpebral closure was rarely observed in cats, even at 20 mg/kg, but staring, vocalization and emesis occurred in more than half the animals tested. In rhesus monkeys, 0.5-1 mg/kg of molindone curtails aggressiveness for 2-3 h. With increasing dosage, the degree and duration of docility are correspondingly increased but more gradually than after similar increments in the dosage of chlorpromazine.

Molindone also affects other responses frequently used to identify neuroleptics4. For example, the emesis induced in dogs by intravenous injections of 0.1 mg/kg of apomorphine hydrochloride is antagonized by molindone, orally administered at 0.5-1 mg/kg. Catalepsy and hypothermia can be demonstrated in rats and mice at oral doses of about 5-15 mg/kg. Finally, molindone inhibits the pressor responses of epinephrine and 5-hydroxytryptamine in anaesthetized dogs, but at intravenous doses which are about ten times higher than equiactive doses of chlor-

promazine.

Table 2. EFFECTS OF MOLINDONE IN RODENT ANTIDEPRESSANT TESTS

Test	Species	ED ₅₀ , mg/kg (95 per cen confidence limits)*
Tetrabenazine antagonism	Mouse Rat	2·5 (1·5-4·1) 2·6 (1·4-4·9)
5-HTP potentiation	Mouse Rat	10.0 (7.1-14.0) 20.0 (14.1-28.2)
l-DOPA potentiation	Mouse Rat	12·0 (8·6-16·8) 8·8 (4·6-16·7)

* Estimated by the method of Litchfield and Wilcoxon⁵.

Molindone was administered, orally, 1 h before intraperitoneal injections of 5-HTP and t-DOPA and 5 h before tetrabenazine.

In addition to these characteristic neuroleptic actions, molindone modifies certain responses in rodents which are similarly affected by antidepressant agents (Table 2). The ptosis induced by intraperitoneal injections of 40 mg/kg of tetrabenazine methanesulphonate in mice or 15 mg/kg in rats is antagonized by oral pretreatment with molindone. Using 50 per cent lid closure as the criterion for ptosis, peak activity was observed at 3-5 h in mice and 24 h in rats. Molindone also produces tremors when administered up to 6 h before subthreshold intraperitoneal injections of 50 mg/kg (mice) and 25 mg/kg (rats) of 5-hydroxytryptophan (5-HTP), peak effects occurring after 1-3 h pretreatment. Finally, molindone potentiates certain effects induced by intraperitoneal injections of 100 and 25 mg/kg of 3,4-dihydroxyphenylalanine (DOPA) into mice and rats, respectively. The criterion for DOPA potentiation in mice was the presence of two or more of the following symptoms: pupillary dilatation, exophthalmos, Straub tail, salivation and aggressiveness. In rats, pupillary dilatation alone was used as the criterion for potentiation because most of the symptoms mentioned occur sporadically after independent administration of either molindone or DOPA.

The effects of molindone summarized in Table 2 are similar to those induced by antidepressants of the dibenzoazepine class (for example, desmethylimipramine⁶) as well as by inhibitors of monoamine oxidase (MAO)7. Molindone scarcely affects rat brain MAO activity in vitro, however (50 per cent inhibition at 9.8×10^{-3} molar), using kynuramine as a substrate in the assay system of Krajls; nor does this agent substantially inhibit kynuramine oxidation by brain MAO after oral doses of 20 mg/kg in rats (maximal inhibition of 30 per cent over a period of 24 h). The possibility that molindone is converted into an active metabolite, in vivo, which then competitively reduces enzyme activity cannot be discounted. Yet when molindone is administered orally to rats 30 min after intraperitoneal injections of 50 mg/kg of SKF 525A, the usual potentiation of 5-HTP and DOPA is unaffected while inhibition of a conditioned avoidance response is enhanced and prolonged.

Work is now in progress to measure concentrations of amines in rat brain after treatment with molindone and to attempt to clarify the apparent paradox concerning tetrabenazine antagonism and 5-HTP and DOPA potentiation, on one hand, and antagonism to the effects of amphetamine, on the other. Although the ultimate clinical disposition of this unusual psychopharmacological agent has not been determined, a recent preliminary investigation has demonstrated its antipsychotic activity.

Reversal of Reserpine-induced Hypothermia by Pharmacological Agents other than Antidepressants

It is known that antidepressants reverse or antagonize many of the effects of reserpine. A widely used test for the detection and evaluation of antidepressants is based on their calorigenic action in reserpinized mice1. In this test all types of clinically useful antidepressants are active but the test is not specific for this class of compound. Potent pharmacological agents such as aspirin, chlorpromazine and morphine, none of which is a clinically useful antidepressant, are accepted as positive by the test. Jori, Paglialunga and Garattini2 have shown that the calorigenic action of desipramine in rats was antagonized by α and β-sympathetic receptor blocking agents. Interest in the mechanism involved, and the possibility of making the test more specific, prompted an investigation of the action of α and β -blocking drugs on the calorigenie action of non-antidepressant compounds in mice.

Male mice (Alderley Park, No. 1, specific pathogen free) weighing 19-21 g were treated with reserpine (2 mg/ base/kg, subcutaneously) and 17 h later were dosed with saline (controls) or a subcutaneous injection of an a or β-blocking drug. Fifteen minutes later, the drug or saline was given orally. Gastric temperatures were

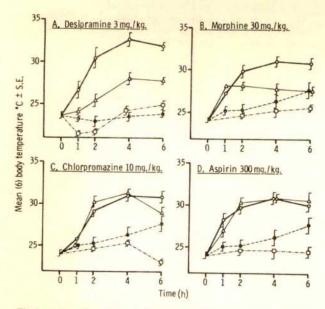

Fig. 1. Antagonism of the calorigenic action of compounds given orally. $A, \bigcirc -\bigcirc$, Desipramine hydrochloride, 3 mg base/kg; $B, \bigcirc -\bigcirc$, morphine hydrochloride, 30 mg base/kg; $C, \bigcirc -\bigcirc$, Chlorpromazine hydrochloride, 10 mg base/kg; and $D, \bigcirc -\bigcirc$, aspirin, 300 mg/kg. Groups of six mice on each treatment received reserpine phosphate, 2 mg base/kg subcutaneously 17 h before 0 h. Phenoxybenzamine, 30 mg base/kg, $\triangle -\triangle$, and propranolol hydrochloride ('Inderal'), 30 mg base/kg, $\square --\square$ were given subcutaneously 15 min before animals treated with A, B, C or D at 0 h. Controls, $\blacksquare ---\blacksquare$, received reserpine 17 h before, and saline at 0 h.

measured using an oral probe and electrical thermometer as described previously³. Temperatures were taken immediately before dosing with the calorigenic agent and at intervals of 1, 2, 4 and 6 h thereafter.

Fig. 1A shows the calorigenic effect of desipramine and Figs. 1B, C and D that of three compounds which, although they are potent pharmacological agents, are not clinically useful antidepressants. The α -receptor blocking agent phenoxybenzamine given at a dose of 30 mg/kg only partially blocks the calorigenic action of desipramine and morphine. The calorigenic effect of chlorpromazine was not significantly affected by phenoxybenzamine at the dose used (30 mg/kg).

The β -blocking drug, propranolol, at a dose of 30 mg/kg completely antagonized the calorigenic action of desipramine and the other compounds. The temperature of control mice rose significantly during the course of the experiment (Figs. 1B, C and D), but the mean temperature of the propranolol-treated mice was lower than that of controls and was not significantly different from the temperature at 0 h.

Selective blockade of either α or β -sympathetic receptors does not help in differentiating between the action of antidepressants and non-specific compounds in the reserpine hypothermia test. The results are compatible with the hypothesis that antidepressants and non-antidepressant compounds such as aspirin, chlorpromazine and morphine are, like antidepressants, producing their calorigenic action in reserpinized mice through an adrenergic link. The sympathetic receptors involved in the mediation of this effect appear to be more sensitive to β -blocking drugs than to α -blocking agents.

Opening and Closing of Eyes and Signs of Psychomotor Excitation resulting from Stimulation of the Putamen in Cats

EVIDENCE from electrophysiological and behavioural experiments and from pathological conditions in man suggests that the functions of the putamen and caudate nucleus are inhibitory in nature. Electrical stimulation of the caudate, however, also gives rise both to electrophysiological excitation¹⁻³ and, from the point of view of behaviour, to facilitatory effects involving contraversive turning of the whole body⁴⁻⁶. We have shown that the inhibitory phenomena previously associated with the putamen⁷ are similarly concerned with excitatory effects.

The putamen was stimulated electrically in conscious unrestrained cats by means of implanted electrodes in which the tips (1 mm uninsulated) were located 2 mm apart one above the other. Square wave pulses lasting 3 msec were applied at frequencies varying from 2-30 c/s, the parameters being monitored by an oscilloscope. The effects of stimulating at 180 different foci, verified by subsequent histological examination, were examined by analysis of filmed records of behaviour taken at the time.

In the resting cat stimulation of certain foci, detailed later, gave rise to excitatory behavioural effects: the ears were flattened and retracted, the palpebral fissures (but not the pupils) were dilated (Fig. 1f and g) and sometimes piloerection occurred. When stimulation was continued

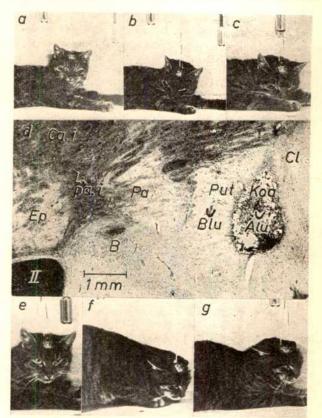

Fig. 1. Stimulation of the points Alu and Blu (see d) at 30 c/s causes an arousal effect with eye opening (a). During stimulation at 8 c/s at the same points the eyes are half closed (b), whereas stimulation at 4 c/s causes a closing of the eyes and a sleep like attitude (c). (d) Sagittal section through the brain of a cat showing some of the stimulation points which produced these effects. The track of the stimulating electrode and point Blu are located in the middle of the putamen. The stimulation point Alu lies in the rostral putamen within the coagulation focus produced by electrocoagulation at the end of the experiment. B, Basal nucleus; Ca. i, internal capsule; Cl, claustrum; Bp, entopeduncular nucleus; L. pa. i, lamella pallidi interna; Pa, pallidum; Put, putamen. Stimulation of the point Blu also elicited a backward dropping of the ears (f) as well as a moving backward of the cat (g) as a sign of excitation.

Compare the attitude before the stimulation (e).

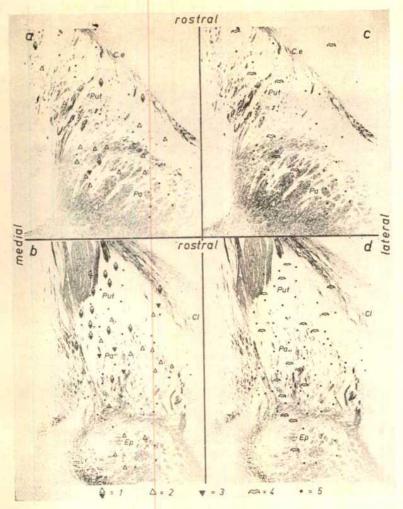

Fig. 2. Horizontal sections at two different levels of the basal ganglia (1.5 mm apart) showing the sites of the stimulating points producing contrary eye effects (opening and closing of the eyes) and/or of psychomotor excitation. The contrary effects (a and b, 1) are mostly elicited in the putamen and opening of the eyes alone (2) chiefly in the pallidum and entopeduncular nucleus. The points producing psychomotor excitation (4) are chiefly found in the putamen (c and d). In the pallidum only the medial region contains similar points. These, however, could be a result of the structure of the efferent pathway of the caudate (c) and putamen (d). (3) Closing of the eyes; (5) negative effects; C.e, external capsule; Cl, claustrum; Ep, entopeduncular nucleus; Pa, pallidum; Put, putamen.

or repeated, the animal also raised its body from the ground. These movements differ from those of the ears and head which are elicited by stimulating the basal nucleus8 or midbrain9 and from those which follow excitation in the region of the posterior commissure10 in so far as the palpebral fissures are then narrowed rather than dilated as in this experiment.

The foci from which such signs of a psychomotor excitation could be obtained were distributed unsystematically throughout the putamen. Seven of the eleven foci (Fig. 2c and d) giving rise to this effect were located within the basal putamen and, as can be seen in Fig. 2d, were particularly concentrated in the marginal regions of the putamen. Outside this area foci from which this effect could be elicited included the region occupied by the basal pallidum, the ansa lenticularis and the entopeduncular nucleus, which corresponds anatomically to that traversed by efferent fibres from the putamen. Several points responding to stimulation were also found in the dorsal margin of the pallidum and the entopeduncular nucleus; they correspond to the position of efferent fibres from the caudate nucleus.

Stimulation of other points within the putamen at a frequency of 30 c/s was, in contrast, followed by opening of the eyes and dilation of the pupils. This was sometimes

accompanied by a behavioural arousal which was demonstrated by the posture of the head. Stimulation of the same points with low frequencies (2-6/sec), however, caused a narrowing both of the palpebral fissures and of the pupils until finally the eyes were closed, although in these conditions the head did not always assume the posture characteristic of sleep (Fig. 1c). The effect of stimulation at 8 c/s on the palpebral fissure depended on the degree to which the eyes were open (wide or half) at the moment the stimulation commenced. Thus an incipient dilation of the palpebral fissure might be converted into a narrowing of the fissure and vice versa

We found no foci in the putamen from which stimulation alone at any frequency would cause the eyelids to close; such foci, however, were found near the putamen. During medium frequency stimulation opening of the eyes without the closing effect was seen six times following stimulation of the putamen, eighteen times from the pallidum and four times from the ansa lenticularis. Such points of stimulation were also found basal and rostral to the putamen.

The finding that both opening and closing of the eyes could be obtained from the same focus depending on the frequencies of stimulation supports the idea that the neuronal elements of the putamen mediate not only an inhibition of gazing movements but also a control mechanism for the reception of visual stimuli. It is surprising that there seems to be no description of this particular phenomenon in the literature dealing with stimulation of the caudate, but similar contrary effects involving sleep and alertness can be elicited from the hypnogenic zone if a supraliminal stimulus is applied11,12 centrum medianum, part of the hypnogenic zone, is known to project to the putamen and caudate nucleus13,14 so that the effects from the putamen described here could belong to the neuronal apparatus representing the hypnogenic system. The relatively frequent arousal and opening of the eyes induced by stimulating the pallidum and the ansa-lenticularis (without eye closing in the

case of low frequency stimulation) cor-respond to the activating influence of the pallidum and its efferent fibres15.

Respiration and Clicking in Quail Embryos

In chicken embryos it is known that lung ventilation begins when, or just before, the embryo pierces the membrane dividing it from the air space, and is well established before hatching. Breathing is intermittent and irregular at first, becoming more regular and more rapid as hatching approaches^{1,2}. It has also long been known that respiration in chicken embryos may be accompanied by a loud regular clicking^{3,4}. Apart from the connexion with respiration, it is not known how these clicks are produced, although in duck embryos observed through holes made in the shell clicks are reported to coincide with movements of inspiration or expiration or both⁴.

In bobwhite and Japanese quail, we have been able to observe that lung ventilation begins about 2.5 and 1.5 days, respectively, before hatching, and it has been shown that the embryos produce many sounds, although usually only of moderate intensity, until about 10-15h before hatching when regular loud clicking begins. Usually these loud regular clicks end before the chick emerges. Recently. we have made simultaneous recordings of clicking and breathing which have thrown more light on their relationship and perhaps also on the development of lung ventilation in avian embryos. Methods of recording will be described elsewhere. Briefly, for sound the egg rests on three mutually perpendicular piezoelectric ceramic ele-The system gives a calibrated flat frequency response over the audio range. A second instrument measures the pressure changes in the air space occurring with breathing (and, of course, also heart and limb) movements. This system can measure to about 0.01 mm of water differential and can be used at the same time as the sound recording. Apart from a small hole in the shell over the air space, which is sealed by the pressure transducer, there is no interference with the embryo.

Records show intermittent and irregular patterns of early respiratory movements (Fig. 1) and the type of simple pattern which occurs as breathing becomes more regular (Fig. 2). An increase in pressure is taken to indicate inspiration. In all illustrations, the top line gives time in seconds and the second shows pressure changes (a rise in pressure is indicated by a deflexion away from the time marks). Of the pair of lines at the bottom, the top line indicates a push and the lower one a pull of the embryo against the transducer. These two lines together form one of the three sound channels (sound envelope only). Figs. 1 and 2 show that this early breathing, which may last for up to about 2 days, occurs without any regular clicking.

Clicks first occur in short bursts and may become loud and regular quite suddenly. We have evidence that the

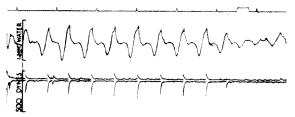

Fig. 3. Bobwhite quail, 5 h before hatching. Compare amplitude of silent (last 3) breaths with that of those accompanied by a click.

Fig. 4. Japanese quail, 4.75 h before hatching.

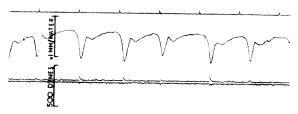

Fig. 5. Bobwhite quail, 29-25 h before hatching.

beginning of loud clicking accompanies or follows a rise in the respiration rate. Moreover, recordings show an increase in amplitude of pressure change (Fig. 3), as well as an alteration in the respiratory pattern, when breathing is accompanied by a click (Figs. 3 and 4). Here the pattern is more complex than that in Figs. 1 and 2, which indicate breathing of the in-out-pause type, although the in-out phase is still apparent. The pattern of pressure change varies somewhat from one egg to another, as the embryo's position within the egg is asymmetrical, and the position of the hole for the pressure transducer will also vary. What is invariable in these records is the timing of the click signals on the sound and pressure records; the click just precedes a sudden rapid change in pressure. This is almost always a change to a rapid rise in pressure (presumed to be a change to breathing in) and occurs between successive in-out movements. during or after the period of regular loud clicking, similar sounds of lower intensity may occur during the in-out phase of breathing (Fig. 5), but in the quail these are less frequent than the regular loud clicking, chiefly considered The sounds associated with this second type of click also show forces of polarity different from the loud regular clicks.

More detailed records can be obtained by recording from only one side of the air space—that is, from the side where the beak protrudes through the torn membrane, or from the opposite side, excluding the beak and below the membrane. For this purpose the shell is removed over that part of the air space to be excluded, and a thin strip of rubber stretched across the gap and glued to the shell. When the edges are sealed with 'Vaseline', it is possible to record from the remaining part of the air space. Records excluding the beak are of the form shown in Fig. 6 (fast recording) where the click coincides with a very rapid lowering of pressure preceding the rapid rise. This suggests that the click accompanies, or could be produced by, an extra, sharp exhalation and inhalation between successive in—out phases of breathing. Recordings from the side of the air space including the beak (Fig. 7) provide a mirror image of this pattern. This mirror image

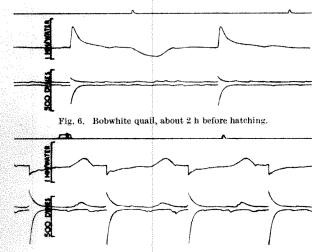

Fig. 7. Bobwhite quail, 15 h before hatching.

effect is to be expected if the greater part of the pressure change recorded now comes from below the membrane. These very fast recordings show best the actual relationship between the sound and pressure signals. Calibration tests show that any delay in the pressure as compared with the sound channel is less than 0.25 msec. sudden lowering of pressure seems to be smoothed over when recordings are taken from the whole air space as in Figs. 3 and 4.

This coincidence of clicking with a change in the rate, amplitude and pattern of breathing suggests that the clicks are produced by a specialized form of breathing in the embryo. This type of breathing begins many hours after lung ventilation has begun and has been stabilized, and usually ends before hatching

Visual Feedback in Hand Tremor

In the experimental situation with which we are concerned here a subject holds a short, stiff, vertical joystick with the finger tips of his right hand and attempts to press to the left with a constant force of, say, 1 kg. His forearm is supported in a horizontal trough. The force exerted is measured by a strain gauge and is made to deflect the spot of a cathode ray tube watched by the subject. The subject's task is to keep the spot at a mark on the tube face corresponding to the required force. He does not succeed, the spot dancing unceasingly around the target position. These errors we refer to as tremor.

Sutton¹ recorded the tremor with this experimental arrangement and performed a frequency analysis. He found (as have other workers in other tasks) that some subjects have a pronounced peak at about 9 c/s in their tremor spectrum. Sutton and Sykes² subsequently made the surprising discovery that if such a subject closed his eyes, or if (without any other alteration in the conditions) the cathode ray tube spot was extinguished, the 9 c/s peak disappeared.

Attempts were made^{2,3} to reconcile this finding with the current view that the 9 c/s peak represents an oscillatory tendency in the stretch reflex loop at spinal level; but experiments, which we need not go into now, led us to doubt this interpretation and to test the alternative hypothesis that the 9 c/s peak involves activity in the larger, visual, feedback loop joystick-display tube-eyebrain-hand-joystick. The test we applied was to introduce time delays into the loop between the joystick and the display tube and to show that this shifted the frequency of the 9 c/s peak. Time delays were simulated by a Padé network giving a phase shift nearly proportional to frequency over the range 1 to 15 c/s. (The principal results have been confirmed in later experiments using genuine time delays from a magnetic tape device.)

The results of a typical experiment are shown in Fig. 1. The spectrum for the first control run (at the top) has a peak at 8.8 c/s. Introducing a delay of 25 msee shifts this to 8.0 c/s. Larger delays caused larger shifts, roughly in proportion. A quite unexpected feature was the emergence of a second peak at a higher frequency. Occasionally with the longest (100 msec) delays even a third peak appeared, at about 13 c/s. (A questionable example of such a peak is seen in Fig. 1.)

Such experiments show without much doubt that under these conditions the frequency of the 9 c/s peak is determined by visual feedback, but the nature of the potential instability in the visual loop thus revealed is uncertain. Consider a negative feedback system with a time lag in it oscillating in the simplest manner at the frequency at which the time lag introduces π radians (180°) phase

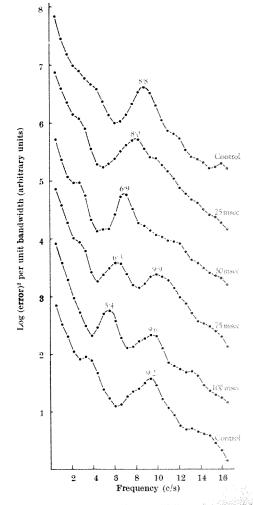

Fig. 1. Power spectra of hand tremor with the various time delays shown inserted between the joystick and the display cathode ray tube. Each recording run lasted 30 sec. The series began and ended with a control run and the runs were made in the order shown, starting at the top. To avoid overlap consecutive spectra are displaced one log unit downwards. The frequencies of the main peaks are given above them in cycles per second. The data were digitized, punched on to paper tape and the power spectra computed on Edsae II in Cambridge.

shift. A frequency of 9 c/s corresponds to 55 msec lag. Adding an additional lag of 100 msec would reduce the frequency of oscillation by a factor of nearly three; but the shift in our experiments was always much less than this. Hence the 9 c/s peak is not of this nature. Suppose instead that the 9 c/s peak is a harmonic of some fundamental mode of oscillation at a lower frequency. turns out that if it were the third harmonic, the fundamental being at about 3 c/s (corresponding to an inherent lag of 167 msec), the expected shift in the 9 c/s peak with added delay would be reconciled with the experimental results, and, furthermore, the two higher frequency peaks, when they occur, would fall into place as the fifth and seventh harmonics. This identification has therefore much to recommend it, but, from other considerations, we prefer a different, but closely related, working hypothesis in which the fundamental (if present) corresponds to an oscillatory tendency with π radians of phase shift round the loop, but the higher peaks are not harmonics but separate modes of oscillation with 3π , 5π and 7π radians phase shift. We prefer this hypothesis because it can account (a) for the apparent lack (in most experiments) of a peak at 3 c/s (any mode may be absent if the gain at that frequency is low), (b) for the absence of peaks corresponding to the even harmonics (instability only results when the phase shift is $\pi + 2n\pi$ radians) and (c) for the occurrence of multiple peaks not in any simple harmonic relation when frequency dependent lags are introduced. These last observations will be described in the full account of this work now in preparation.

It should be mentioned that not all 9 c/s peaks are visually determined. By slightly altering the mechanical conditions of the task Dymott and Merton⁴ have produced good 9 c/s peaks in runs with the eyes shut.

Dissociation of the Pressor and **Antidiuretic Activities of Synthetic** Arginine Vasopressin by Heating at pH 10

Zaoral, Kolc and Šorm¹ showed that the analogue of arginine vasopressin in which the arginine is in the D rather than the L-configuration, [8-D-arginine]-vasopressin, has ten times as much antidiuretic as vasopressor activity. This finding allows an explanation for the early report by Heller² that a similar dissociation of activities was obtained when 'Pitressin' (Parke, Davis and Co.) was heated at alkaline pH. One of the effects of such treatment on polypeptides is racemization of their constituent amino-acids, and, if one can generalize from the behaviour of adrenocorticotrophin (ACTH), one of the amino-acids most likely to racemize is arginine3.

Fraser⁴ confirmed Heller's² results when he assayed antidiuretic activity by subcutaneous injection of the hormone into rats or dogs. When, however, he administered the hormone intravenously, to dogs he found that the antidiuretic potency of the treated hormone, so determined, was the same as its vasopressor potency. He attributed the discrepancy between the antidiuretic potencies, determined by the subcutaneous and intraven-

ous routes, to the presence of amino-acids derived from hydrolysis of the hormonal peptide, because Noble, Rinderknecht and Williams⁵ had shown that amino-acids enhance the antidiuretic effects of subcutaneously injected vasopressin. Noble et al.5, however, found that an aminoacid concentration of about 1 per cent was necessary to demonstrate this effect and this would represent a concentration of the vasopressin used by Fraser ('Postlobin-V') of $2{,}000$ U/ml., whereas Heller's incubation mixture contained only 0.5 U/ml.

In view of the recent findings of Zaoral et al. we decided to reinvestigate the action of mild alkaline treatment on synthetic arginine vasopressin (provided by Dr D. R. Chambers of Hoechst, Ltd.). The peptide (1.15 mg) was dissolved in 5 ml. of 0.05 normal acetic acid and this served as the stock solution. For each experiment, 1 ml. stock solution was diluted to 10 ml. with a carbonate-bicarbonate buffer of pH 10 (made by diluting 10 ml. of molar sodium carbonate and 20 ml. of molar sodium bicarbonate to 500 ml.) and a sample was immediately placed in the cold until assayed. The remainder of the solution was distributed in 1 ml. portions among ampoules which were then sealed and heated in a boiling-water bath for the required time. At the end of the heating period the ampoules were cooled and stored in the refrigerator until assayed-which in all cases was on the same day. Antidiuretic activity was determined by intravenous injection into rats according to a modification of the method of Jeffers, Livezey and Austin⁷. Vasopressor activity was also determined in rats by Dekanski's method. commercial preparation of natural arginine vasopressin, 'Tonephin' (Hoechst AG, Frankfurt), was used as standard in all assays.

Table 1 shows that heating at pH 10 does cause a dissociation of the antidiuretic and pressor potencies of arginine vasopressin even when the former is measured by an intravenous method. Heating the hormone for periods of 30 min or longer increased the ratio of antidiuretic to vasopressor activity from approximately 1:1 to just under 2:1, although the absolute amount of each activity was considerably reduced. This result is compatible with the formation of some [8-D-arginine]vasopressin as one of the reaction products. The ten-fold difference between antidiuretic and vasopressor potencies of heated hormone found by subcutaneous antidiuretic assay^{2,4} may be due in part to a delayed absorption caused by the amino-acids derived from hydrolysis of the hormone⁴, but perhaps more likely to the slower absorption of a modified hormone.

We thank Miss Anne Coxall for technical assistance.

Anti-inflammatory Activity of d- α -Tocopherol (Vitamin E) and Linoleic Acid

CELLULAR membranes, especially those of lysosomes, become unstable in a variety of conditions—reviewed by Thomas—for example, the Arthus and Schwartzman reactions; exposure to streptolysin, ultraviolet light and carbon tetrachloride; and the muscular dystrophy of tocopherol deficiency1. Cortisone is inhibitory in most of these conditions, and has been shown to have antioxidant properties2, so we thought that other antioxidants might be effective anti-inflammatory agents. Lysosomal membranes, as well as other membranes, are composed largely of lipids and we also thought that their lysis could result from damage to such structural lipids. This idea is supported by work of Austin and Brocklehurst3, showing that the release of histamine and slow reacting substances (SRS-A) from sensitized guinea-pig lung is inhibited by long chain fatty acids. Accordingly d-a-tocopherol (vitamin E) and linoleic acid were tested as anti-inflammatory agents and found to be effective.

Male Holzman rats weighing 120-160 g at the beginning of the experiments were given adjuvant consisting of 3 mg of heat killed Mycobacterium butyricum (Difco) in 0.1 ml. of olive oil injected into the subcutaneous tissues of the tail (day 1). The rats were then divided into test groups. The lesions were graded from 0 to 4 on the following basis: 0, no apparent lesions; 1, up to four lesions up to 3 mm in diameter; 2, more numerous or larger lesions than in grade 1, up to a maximum of 1 cm in diameter; 3, lesions larger than 1 cm often becoming confluent but not yet involving an entire extremity; 4, confluent involvement of one or more extremities with swelling of the entire extremity of two or more times the normal diameter. The scores of rats in the different groups on days 12, 13, 14, 15, 17 and 19 were treated statistically to provide the mean and standard deviation for each group. The treated groups were compared with the controls by the t test.

This adjuvant treatment produced lesions between the eighth and twelfth days and they rapidly grew worse, reaching a maximum usually before the nineteenth day. Most animals in the control groups developed diffuse swelling of the extremities which was so severe that the limbs were three to four times the normal diameter within 5-6 days of the onset of swelling. These rats had severely impaired mobility. Only one of the twenty-one rats in the control group developed no gross lesions, while 85.7 per cent developed grade 4 lesions.

Linoleic acid and d- α -tocopherol were given intraperitoneally in attempts to inhibit the development of lesions. Twenty-four rats were each given 0.6 ml. of tocopherol/kg of body weight once a week, beginning on the day of administration of adjuvant. Of these (Table 1), 29.2 per cent developed no detectable lesions, 54.2 per cent developed grade 1 to 2 lesions and 16.7 per cent developed grade 3 and 4 lesions. The differences between controls and the tocopherol-treated groups on days 12, 13, 14, 15, 17 and 19 were well below the 0.001 level of

significance.

Twenty-four rats were each given linoleic acid, 1.33 ml./kg of body weight on the day when adjuvant was given (day 1) and 0.5 ml./kg of body weight daily thereafter. Previous testing indicated that linoleic acid induced local bleeding and haematoma formation, and that this dosage approached the limits of tolerance for the duration of the experiments. The inhibition produced (Table 1) was similar in degree to that produced by tocopherol and the difference from the controls on each of the respective days was significant below the 0.001 level.

The effect of delaying the initiation of treatment to the fifth or ninth day after adjuvant administration was investigated. Delaying the first injection of linoleic acid to the fifth day produced results similar to those after giving the first injection on day 1. Delaying the first administration of tocopherol until the fifth day, or of linoleic acid to the ninth day, however, resulted in the development of lesions with an average severity intermediate between the controls and the other treatment groups. Delaying the first tocopherol treatment until the ninth day resulted in no significant difference from the controls, and continued treatment produced no gross evidence of improvement. The rats, however, seemed to suffer less discomfort and immobility, and to be less irritable.

One possible explanation for the decreased influence of the linoleic acid and tocopherol when treatment started late is that these substances must be incorporated into cellular structures to be of maximum benefit. If this explanation proves to be correct, the time required for incorporation of tocopherol would be longer than for linoleic acid.

It is possible that the phagocytic or intracellular handling of the adjuvant, or the immunological response to the constituents of the adjuvant, is altered by the treatments outlined, and tests are in progress to determine whether this is so. On the other hand, tocopherol is well known as a biological antioxidant and free radical seavenger*. Linoleic acid is an effective inhibitor of damage by Xirradiation⁵, which is mediated by free radicals. facts together with the anti-inflammatory activity that we are reporting here suggest that inflammation of this type involves lipid peroxidation and its associated production of free radicals. As mentioned here, cortisone is a stabilizer of membranes against a variety of agents, and it is also effective in inhibiting adjuvant-induced arthritis. Weissmann and Thomas have reported that cortisone also possesses antioxidant properties2.

Linoleic acid may also act either as a competitive substrate for whatever processes attack cellular lipids, or as a ready replacement for damaged cellular lipids.

Table 1. DEVELOPMENT OF LESIONS IN TREATED RATS

Group	Total No. in group	No. o	f rats in e	each grou espective 2		1 to 4	Mean	Signt- flexace level
1	21	1 (4·8%)	-	(4·8%)	1 (4·8%)	18 (85·7%)	3-7	Special
2	24	7 (29·2%)	6 (25·0%)	7 (29·2%)	(4·2%)	(12·5%)	1.6	Less than 0-001
3	24	11 (45·8%)	3 (12·5%)	(4.2%)	4 (16•7%)	(20·8%)	1*5	Less than 0.001
4	6		1 (16·7%)	2 (33·3%)	(33·3%)	(16.7%)	2.5	0.01
5	6				4 (66•7%)	(33·3%)	3*3	Greater than 0.5
6	6		(16·7%)	4 (66·7%)	(16•7%)		2-0	Less than 0 001
7	6	1 (16·7%)		1 (16·7%)	(33·3 %)	(33·3%)	2-7	Greater than 0-05

Groups 2-7 received adjuvant plus the treatment described here. The score for each group was compiled from the highest individual scores within the group. The significance level is that for day 19, comparing the respective groups with the control group (1). (1) Adjuvant only; (2) tecopherol, 0.6 ml./kg body weight/week, starting on the day of adjuvant administration (day 1); (3) linoleic acid, 1-33 ml./kg body weight on day 5; (5) as group 4, but starting on day 9; (6) linoleic acid, 1-33 ml./kg of body weight on day 5 followed by 0-5 ml./kg body weight daily thereafter; (7) as for group 6, but starting on day 9;

Lipids are important both in the structure and function of mitochondria, and mitochondrial oxidative phosphorylation declines with peroxidation. Tocopherol also may function in conjunction with sulphydryl sites associated with respiratory enzymes. Lysosomal instability and enzyme loss may also result from lipid peroxidation, and lysosomal enzymes may attack mitochondrial components, so that the conditions are available for a vicious cycle in which impairment of cellular metabolism and attack on structural elements may each cause further damage to the other. Such a cycle could be inhibited or broken by antioxidants.

We thank the Arthritis Foundation, Southern California Chapter, for their financial support and Dr Paul Yahiku for statistical help, as well as the Loma Linda University Computational Facility supported in part by a grant from the US National Institutes of Health.

Types of Secretory Neurones in the Pre-optic Nucleus of the European Eel, Anguilla anguilla L.

Knowles and Vollrath¹, working on the ultrastructure of the neurohypophysis of the eel, Anguilla anguilla, have shown that it contains three distinct types of neurosecretory axons separable by the size and appearance of their elementary granules, and termed types A1, A2 and Brespectively. A type fibres contain elementary granules of diameter greater than 1000 Å, whereas in the B type fibres they are less than 1000 Å. There is some evidence that only the A type fibres are stained by so-called neurosecretory dyes. For this reason and because the neurones of the pre-optic nucleus are the only ones in the hypothalamus of fishes that stain with these dyes, it seems likely that the A type fibres originate from these neurones. The detailed morphology of the entire hypothalamohypophysial complex of the eel has been described2 and a good deal is known of the histology of the pre-optic nucleus from optical microscopy (see ref. 2 for references) although these studies have so far failed to identify two cell types that might give rise to the two A type fibres of the neurohypophysis.

We have now examined the pre-optic neurones of the eel by electron microscopy and by optical microscopy of

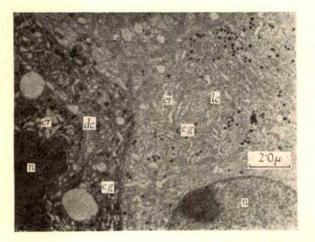

Fig. 1. "Dark" cell and "light" cell adjoining. Note differences in electron density of both cytoplasm and nucleus. dc. Dark cell; eq, elementary granules; er, endoplasmic reticulum; lc, light cell; n, nucleus. Stained with uranyl acetate.

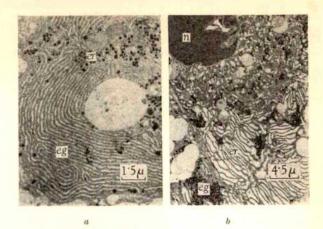

Fig. 2. a, Peripheral region of "light" cell showing endoplasmic reticulum, elementary granules and other inclusions. Elementary granules; er, endoplasmic reticulum; n, nucleus.

sections cut about 1 µ thick from material fixed and embedded for electron microscopy and stained with Azur II. These studies have revealed two easily separable types of neurones. At the level of ultrastructure the perikarya of both are divisible into two distinct regions, a zone in contact with the nucleus and continuous with the axoplasm and a polar cap of endoplasmic reticulum containing some large electron lucent vesicles. In the perinuclear zone, mitochondria, Golgi bodies, inclusions of differing sizes and electron densities and the so-called elementary granules are present. The most immediately obvious difference between the two types of cell is that one is appreciably more electron dense than the other, especially after staining with uranyl acetate, this difference extending to both cytoplasm and nucleus (Fig. 1). The functional significance of the two cell types is unknown, and so they are named "dark" and "light" cells, respectively. It may be noted that the dark cells also stain more deeply with Azur II and that both cell types are present in both regions of the pre-optic nucleus.

A further difference between the two cell types concerns the appearance of the endoplasmic reticulum. In the dark cells the cisternae are swollen and irregular whereas in the light cells they are narrow and regular, the lamellae being arranged in parallel concentric rows in "fingerprint' fashion (Fig. 2). The difference between the sizes of the elementary granules is, however, the most important distinguishing feature. By measuring the largest elementary granules in a number of each of the cell types a mean diameter of 2150 ± 30 Å was obtained for the dark cells and of 1627 ± 31 Å for the light cells. These sizes are identical to those obtained for the elementary granules in the A1 and A2 type fibres respectively in the neurohypophysis and the difference between them is highly significant (P < 0.001). Although the sizes recorded here are slightly larger than those given by Knowles and Vollrath¹, the difference between the diameters of the two kinds of granules is closely similar and it seems possible that the discrepancy can be accounted for by differences in fixation techniques.

Our first interpretation of the differences between the two cell types was that they represented different levels of activity, but both cell types appear highly active and there are no intermediate stages. Furthermore, the difference in size between the elementary granules of the two types seems to confirm that they are distinct and it can be supposed that each gives rise to one of the two A type fibres described by Knowles and Vollrath¹ in the neurohypophysis of the eel.

The physiological significance of the two neuronal types has not been determined although, because two octapeptide hormones-arginine vasotocin and ichthyotocin-have been identified in the neurohypophysis of fish³, and Lederis⁴ has shown that at least the former resides in elementary granules, one of the neurone types may be vasotocinergic and the other ichthyotocinergic. Such a possibility can be tested only by isolation of the two types of neurones and identification of the hormones they produce.

We thank Dr Gunther Sterba for allowing us to report that in recent work on the pre-optic nucleus of the carp, Cyprinus carpio, he has identified dark and light cells

very similar to those described above.

Enzyme Induction in Man caused by Smoking

HIGHER animals may change in their response to drugs because of a decrease in the sensitivity of drug receptor sites in the organism, or because of accelerated drug metabolism. The latter has been explained on the basis of drug induced stimulation of liver microsomal enzymes, for example, many compounds have been listed which induce microsomal oxidizing enzymes in rats, and phenobarbital has been shown to stimulate the metabolism of the anti-coagulant coumarin in man2. We now report the induced enzyme metabolism of nicotine in man by tobacco smoking.

The recovery of nicotine from urine after administration by (a) intravenous injection; (b) inhalation of nicotine vapour; and (c) smoking to male subjects (age 21-40 yr, not taking other drugs) whose urine was maintained acidic was determined by gas-liquid chromatography3. Maintenance of an acid urine minimizes intra- and intersubject variations in excretion of bases4-6, and in these conditions the excretion of unchanged nicotine is virtually complete in 8 h. (Smoking (c) was measured from the amount of nicotine in the main stream smoke7.)

The results of the nicotine experiments are shown in Fig. 1; variation between subjects was small. Whatever the route of administration, the percentage recovery of nicotine in the urine remained constant within ±8 per cent for each subject, and was greater for non-smokers (55-70 per cent) than for smokers (25-50 per cent) (Fig. 1). Non-smokers were not given nicotine more than once every 3 weeks during the trials; nicotine recoveries were the same throughout the trial period.

The increased metabolism of nicotine by smokers cannot be attributed to the increase in the nicotine dose resulting from inhalation, because the recovery of nicotine excreted unchanged in the urine was the same for subjects after intravenous injection and smoking, and was also the same when subjects inhaled or deliberately non-inhaled while smoking, that is, recoveries of nicotine in the ranges of doses used were not affected by the dose of nicotine absorbed.

Subjects were classified as non-smokers if they did not smoke more than thirty eigarettes or three eigars a year. One current non-smoker (G. O. J., Fig. 1) had been a heavy smoker some years before the trials; a lower recovery of nicotine was observed in this subject than in other non-smokers. It is possible that the tolerance to

nicotine lasts for at least 2 months, for one smoker (J. F. T., Fig. 1) abstained from normal eigarette smoking during a 2 month period of the trial; the nicotine recovery remained as expected for a smoker.

Thus the clear difference in nicotine recovery in smokers and non-smokers indicates that habitual smoking induces enzyme metabolism of nicotine. Preliminary results indicate that it is not by an increased metabolism to cotinine because recoveries of cotinine from the urine of smokers and non-smokers were comparable.

Others have demonstrated for the dog and rabbit, and for the rate, that chronic exposure to nicotine leads to a decreased percentage excreted unchanged in the urine. Werle and Uschold injected rats with nicotine daily for 10 days and from their results concluded that progressively

less was excreted in the urine.

Indirect evidence of an acquired metabolic tolerance to nicotine in man by tobacco smoking has been presented by Rottenstein and co-workers10; intravenous injection to smokers did not cause nausea but in non-smokers the same dose produced nausea and vomiting.

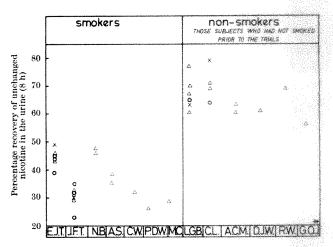

Fig. 1. The percentage recovery of unchanged nicotine in the urine (8.b) of human subjects with various routes of drug administration; urine maintained acidic. \bigcirc , Intravenous administration (1-0-20 mg); \times , inhalation of nicotine (0-1-0-5 mg); \triangle , smoking (0-05-28 mg); * This subject had been a heavy smoker, but had stopped smoking some years before the trials.

The rate of development of the acquired tolerance to nicotine and the possibility that nicotine or other constituents of tobacco smoke stimulate the metabolism of other compounds is being investigated.

We thank the Tobacco Research Council for financial assistance and for supplying the standard eigarettes and We also thank the volunteers for their cocigars. operation.

Voltage Fluctuations of Neural Membrane

THE resting membrane potential of the frog Ranvier node shows fluctuations for which, between 1 and 10,000 rad/sec, the power/cycle of bandwidth is inversely proportional to frequency (l/f noise), and for frequencies of less than about 1 rad/sec there may be an increase in the negative slope of the plot of log noise power against log frequency^{1,2}. This communication reports experiments on the amplitude distributions of the membrane noise voltage.

The arrangement was similar to that described before¹: a three node preparation and a three terminal version of the electronic feedback isolation arrangement according to Frankenhaeuser² were used. The membrane potential of the middle node, lying in a pool containing Ringer or a testing fluid, was measured through one of the adjacent nodes, bathed in isotonic potassium chloride, by means of KCl-agar bridges to silver-silver chloride electrodes connected to a low noise, chopper stabilized electrometer amplifier. The membrane potential could be varied by means of d.c. injection through a 1,000 megohm series resistor through the other adjacent node. After filtering through a high pass filter (time constant 2 sec) to eliminate the d.c. component of the membrane potential and after further amplification the amplitudes of the noise voltage were sampled with 1.5 µsec pulses at a rate of 1,000/sec. The amplitude of each sample was stored in the memory of a 128-channel scaler-analyser, with a channel width of 100 µV of the input. From the resulting amplitude distribution the standard deviation, indicative of noise intensity, and the third moment $(\Sigma x^3/N)$, where x is the noise amplitude and N the total number of samples). indicative of degree of skew, were calculated.

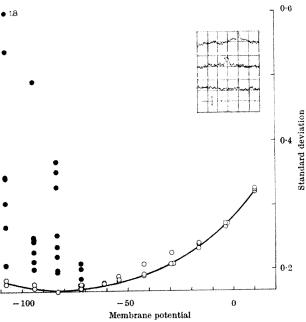

Fig. 1. Standard deviation of amplitude distributions of membrane noise voltage plotted against membrane potential.
O. Gaussian distributions;
o. positively skewed distributions. Length of noise tracks analysed at each point was 12·5 sec. Inset is membrane noise (bandwidth 0·5-3.000 c/s) at a membrane potential of -90 mV. Units: 1 mV and 10 msec. A single miniature depolarizing potential is visible in the upper track, and a group of two in the second, while none are present in the third track.

The relationship between noise intensity and membrane potential is shown in Fig. 1. Overall noise intensity is lowest for membrane potentials between -60 and -70 mV for this particular node. For smaller membrane potentials the spread of the intensities increases. This is because of a pronounced positive skew in the amplitude distributions. The intensity of the Gaussian noise component is minimal

at the (supposed) level of the potassium equilibrium potential, which suggests that there is a relationship between Gaussian noise and passive potassium ion flux through the membrane.

Interfering with active ion transport (by the addition of 2,4-dinitrophenol to the Ringer in the bath together with an atmosphere of pure nitrogen) did not influence the Gaussian noise, nor did replacement of sodium chloride by saccharose. Replacement of sodium chloride by potassium chloride, however, shifted the Gaussian noise minimum towards zero membrane potential, the minimum either coinciding with the small remaining resting potential or lying between this potential and zero. Likewise it was found that 5 per cent tetra-ethylammonium Ringer, which is known to reduce the potassium conductance of frog node^{5,6}, reduces the intensity of the Gaussian noise component.

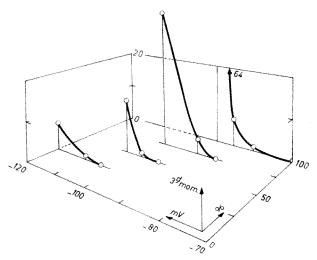

Fig. 2. Three dimensional representation of the relation between skewness (third moment), sodium chloride concentration in the bathing fluid (percentage of that in Ringer) and membrane potential. Length of noise tracks analysed at each point was 100 sec.

We conclude that the Gaussian noise component is related to the passive flux of potassium ions and that its minimum indicates the potassium equilibrium potential. The position of the range of transition from Gaussian into skewed noise is independent of the actual resting membrane potential recorded in the absence of d.c. injection. The tracks of skewed noise (Fig. 1, inset) show that skewness is caused by the irregular occurrence of miniature depolarizing potentials, spiked and with amplitudes of the order of 1 mV and lasting about 1 msec. These potentials occur both singly and in clusters, which vary from groups of a few additive miniature depolarizing potentials to high-amplitude, long-duration depolarizing bursts of noise (described by del Castillo and Katz⁴) in which the unit potentials cannot be distinguished. These phenomena suggest that passive membrane sodium mechanisms are involved.

Interfering with active ion transport did not influence skewed noise, which excludes active transport and neither did replacement of chlorine ions by sulphate ions nor the addition of 5 per cent tetra-ethylammonium to the bathing Ringer solution, which excludes the involvement of chlorine and of potassium ions. Partial replacement of sodium chloride by saccharose resulted in a reversible shift of the transitional range towards more hyperpolarized levels, the shift increasing with the amount of sodium replaced (Fig. 2).

We conclude that skewed noise is related to spontaneous batchwise fluxes of sodium ions through passive transport sites within the membrane.

We thank Dr J. W. Duyff for his help. This work was supported in part by a grant from the Netherlands Organization for the Advancement of Pure Research.

BIOLOGY

DDT Residues in Pacific Sea Birds: a Persistent Insecticide in Marine Food Chains

THE accumulation and biological concentration of DDT and its metabolites* within food chains of terrestrial1, freshwater² and estuarine³ ecosystems have been well documented. Significant residue concentrations have occasionally been reported in marine organisms, but these have usually been attributed to local sources of contamination4. The present study, which is based on analyses of collections of birds, fish and invertebrates from Pacific Ocean localities, indicates that DDT is also a component of marine ecosystems and that pelagic species may accumulate high concentrations of DDT residues. results of the work with fish will be published elsewhere.

Specimens collected for analysis were frozen and stored at -15° C. Some conversion of p,p'-DDT to p,p'-DDD may occur in these conditions, and so the reported values of these two compounds may be somewhat lower and higher, respectively, than those occurring in nature. Tissues, eggs and whole birds were digested with a mixture of acetic and perchloric acids, and the lipid fraction containing the pesticide was extracted from the diluted digestion mixture with petroleum ether or N-hexane7. Recovery of DDT from fortified tissue samples averaged 96 per cent. Lipids were removed by passage of the extract through a modified Davidow column. Because aldrin, dieldrin and similar compounds are destroyed by this treatment, some extracts were prepared by the method of Bligh and Dyers, and were cleaned on 'Florisil' columnss. Analyses of the purified extracts were performed on a Microtek 220 gas chromatograph, equipped with an allglass system and an electron capture detector. chromatograms were performed isothermally (190°C) on 3 per cent QF-1 or 5 per cent SE-30 on 'Chromosorb W', 80-100 mesh treated with hexamethyldisilazane or on 10 per cent DC-200 on 'Gas-Chrom Q' (ref. 5). The carrier gas was nitrogen. Identification of the chlorinated hydrocarbons recorded in the western gull and brown pelican was confirmed by thin-layer chromatography10.

Residue levels in the resident California species (Table 1) were considerably higher than those in the northern migrants (Table 2) which spend the winter months off the California coast. It is not possible to estimate how much of the residue carried by the northern birds originated in California waters. The shearwaters (Table 2), which are

* DDT residues include the two isomers of DDT, p, p'-DDT and o, p'-DDT and the metabolic derivatives of p, p'-DDT: p, p'-DDE, p, p'-DDD, and p, p'-DDMU: p, p'-DDT, 1,1,1-trichloro-2,2-bis(p-chlorophenyl)ethane; o, p'-DDT, 1,1,1-trichloro-2-(o-chlorophenyl)-2-(p-chlorophenyl)-hane, p, p'-DDE, 1,1-dichloro-2,2-bis(p-chlorophenyl)ethylene, p, p'-DDD, also known as TDE, 1,1-dichloro-2,2-bis(p-chlorophenyl)ethylene; p, p'-DDMU, 1-chloro-2,2-bis(p-chlorophenyl)ethylene.

strictly pelagic migrants from the southern hemisphere. contained as much as, or more pesticide than, the local birds. The sooty shearwater and the slender-billed shearwater are known as the mutton birds of New Zealand and of Bass Strait, Australia, respectively, and are a traditional source of food for the local human populations. After the nesting season both species migrate northwards across the Equator. During the summer months many thousands of sooty shearwaters are present in Monterey Bay. DDT has been extensively used for mosquito control in many countries and may therefore be relatively more prevalent in some areas of tropical seas.

A significant fraction of the pesticides present in breeding females may be passed on to the eggs. Three female Cassin's auklets, which lay a single egg each season, were collected with their eggs from burrows on the Farallon Islands. The total concentrations of residue in the eggs ranged from 9.4 per cent to 32 per cent of the total present in the adult female.

A mean value of 3·1 μg of dieldrin was found in three eggs of the western gull, but dieldrin was not present in the breast muscle of the brown pelican, or in fat samples of the Cassin's auklet. DDMU was detected in almost all avian tissues. It is part of the pathway by which p,p'-DDT is degraded to the water-soluble compounds

Table 1. DDT RESIDUES (p,p'-DDT,o,p'-DDT,p,p'-DDE,p,p'-DDD,p,p'-DDME) IN SEA BIRDS RESIDENT IN CALIFORNIA

DDA and dichlorobenzophenone in the chick embryo11, and so we assume that its presence indicates some amount of DDT metabolism.

We have reported the pesticide content and the individual variation of pesticide content and concentration in collections of eight species of Pacific marine fish⁵. Total levels of DDT residue in tissues of the blue fin tuna (Thunnus thynnus) and the yellowfin tuna (Thunnus albacares) from Baja California, Central America, and the Galapagos Islands ranged from 0·1 to 0·6 p.p.m. Skipjack tuna (Euthynnus pelamis) from waters off Hawaii, the Galapagos Islands, and mainland Ecuador contained somewhat lower concentrations of DDT residue, which ranged from 10 to 100 parts per billion. Fish from California coastal waters contained more residue, but in general total concentrations were 10-20 per cent of those in the Collections of the northern anchovy (Engraulis mordax), English sole (Parophrys vetulus), Pacific jack mackerel (Trachurus symmetricus) and of hake (Merluccius productus) from offshore waters between San Francisco and the Channel Islands north of Los Angeles averaged between 0.2 and 2.8 p.p.m. of total residue: 12.7 p.p.m. were present, however, in anchovies taken off Terminal Island, Los Angeles. Significantly lower concentrations of residue were found in anchovies and English sole from San Francisco Bay. San Francisco Bay receives drainage water from the Sacramento and San Joaquin Valleys, and so it seems unlikely that agricultural run-off can account for the observed distribution of DDT residues in the seas.

Residue levels in several marine invertebrates from coastal localities between Monterey and Point Arena were ten to fifty times lower than those in the fish analysed (Table 3). Most values ranged between 20 and 100 parts per billion. The snail (Thais emarginata) and the common starfish (Pisaster ochraceus) both feed on the mussel Mytilus californianus. No biological accumulation could be demonstrated in the starfish, but the snail contained two to five times the concentrations of residue present in its principal food source collected at the same localities. All the DDT recorded in the purple urchins was present in the gonads at a concentration of 5 parts per billion. No residue, or less than the detectable limit of 1 part per billion, was present in the other tissues of the urchins.

Notation as in Table 1.

Unfortunately, our present knowledge permits only an imperfect estimate of the present and future effects of DDT accumulation in any species. Within the past few years the numbers of the peregrine falcon and the bald eagle have declined and both species have essentially disappeared as breeding birds on the Channel Islands of California (personal observation and records of Mr W. G. Abbott). There is no evidence that the fanatical efforts of egg collectors in the early years of the century or recent pressure from hunters and falconers have been a significant factor. The comparatively high amounts of DDT and its metabolites in fish from the vicinity of the Channel Islands suggest that food chain concentration would result in high levels of residue in fish-eating birds or in species such as the peregrine falcon which feed on other birds. Whether the high pesticide content of the single Cassin's auklet found dead on the Farallon Islands contributed to its death is a matter for speculation.

Reports on levels of residue in tropical areas where DDT is used for mosquito control are as yet lacking. The total DDT residues in the eggs of British sea birds12 and in the tissues of birds from the coastal regions of Holland¹⁸ suggest that DDT contamination is less in European seas, although more dieldrin and endrin are present. The recently published values of DDT concentrations in organisms of a Long Island, New York, estuary³ suggest that contamination in the offshore waters of New England may be as high as in California.

Although chlorinated hydrocarbons in solution or adsorbed to particulate matter are brought by rivers to the sea14, transport by water circulation can scarcely account for the observed distribution of DDT in the sea and its occurrence in very remote areas¹⁵. Chlorinated hydrocarbons readily evaporate with water from the surfaces of marshes and soil16, are found associated with particulate matter in the air17, and are present in the atmosphere as a result of air-spraying operations. Wind transport and subsequent fallout in rain18 might therefore account for the apparent universal occurrence of DDT and its metabolites in the ocean.

Initiation of Courtship by Hypothalamic Implants of Testosterone Propionate in Castrated Doves (Streptopelia risoria)

DAVIDSON¹ in 1966 and Lisk² in 1967 suggested that a system sensitive to androgen, situated in the preoptic and anterior hypothalamic regions, is associated with mechanisms underlying copulatory behaviour in the male rat. This system would seem to be the counterpart of the oestrogen-sensitive systems known to be associated with patterns of female sexual receptivity in the rat3, the rabbit4 and the cat⁵. The problem arises as to whether the male courtship patterns which often precede copulation are similarly linked to discrete androgen-sensitive regions of the central nervous system (CNS). This seems doubtful in male mammals, for mechanisms underlying such patterns are thought to be functionally independent of gonadal hormones. There is preliminary evidence, however, that in the male fowl simultaneous androgenic activation of the preoptic region and an area extending from the palaeostriatum to the lateral diencephalon is required for courtship display?.

My unpublished observations of the decline of courtship after castration in male Barbary doves have shown that chasing, bowing and nest soliciting (equivalent to the patterns termed "driving", "bowing" and "nest demonstration" in the pigeon by Fabricius and Jannsen⁸). displayed by a sexually active male to a female, declined and disappeared within 10 to 20 days of the castration operation, and that such a castrated male became unresponsive to females. The display of these courtship patterns could be re-established by means of daily intramuscular injections of testosterone propionate, which implies that the systems underlying courtship behaviour in this species are androgen-dependent. In order to examine further the possibility that androgens influence discrete regions of the CNS to promote male courtship in birds, the effects of intracerebral implants of testosterone propionate in castrated Barbary dove males have been assessed.

The experimental males were maintained in visual isolation in separate cages. Light was supplied for 13 h/ day and the temperature maintained at 18°-23° C. Each male was tested for 3 min with one of four test females on 4 consecutive days: the females, known to be sexually active, were alternated so that each male interacted with each female. The duration of each male courtship pattern was recorded on a pen-recorder (Cambridge Instruments) from a hide. Males which failed to show chasing, bowing and nest soliciting at each test were not used. Each male was castrated and given four successive daily tests for courtship beginning 25 days after the castration operation. The majority (97 per cent) were unresponsive to the female: the remainder, which showed short durations of chasing, were discarded. At the time of castration, the light was reduced to 8.5 h/day to discourage regeneration of the testes, and maintained at this level for the rest of the experimental period. On the thirtieth day after

castration, each male was implanted stereotaxically with crystalline testosterone propionate fused to the end of stainless steel tubing (33 gauge), one implant being positioned unilaterally in each male and left in place until the end of the experiment. Implanted males were tested on the day after the operation and on 14 successive days after that; on the sixteenth day, experimental males Transverse sections (25μ) were prepared were killed. from the brain of each male and stained for histological examination to localize the position of the implant. The nomenclature used to describe the position of implants in the brain is after Huber and Crosby. No evidence of regeneration of the testes was found from an autopsy carried out on each male; the vasa deferentia of each male were atrophic.

A group of castrated males (N=5) was implanted with testosterone propionate in the region of the nucleus preopticus medialis (PM), and a further group (N=0) in the region of the nucleus hypothalamicus anterior medialis (HAM). All these males showed a response to the hormone: most displayed chasing and nest soliciting, whereas markedly fewer males displayed bowing (Table 1). courtship patterns displayed by implanted males were similar to their normally occurring counterparts, and the sequence of response of males of both groups followed the same trend of development and decline (Fig. 1): thus few males showed a response on the first or second days after implantation, but the majority had displayed chasing and nest soliciting by the fourth and fifth days after implantation. In both groups, the response declined and disappeared within 8-12 days of implantation. There were no significant differences between the peak durations, the response period or the response latency of any of the courtship patterns displayed by the two groups and for further comparisons (Table 2) the results obtained from the two groups have been combined (PM+HAM). These males displayed significantly shorter peak durations of chasing (Wilcoxon matched pairs test, two-tailed, P < 0.05) and bowing (P < 0.01) after implantation than prior to castration; there was no significant difference between peak durations of nest soliciting displayed before castration and after implantation.

Of males (N=8) implanted with slightly larger implants (Table 1) of testosterone propionate 2.5 mm dorsal to the anterior hypothalamus in a region of the neostriatum intermediale (NI) adjacent to the hippocampus and forebrain ventricle, four males gave no response, and the remainder displayed no bowing and only short durations of chasing and nest soliciting. The peak durations and the response periods (Table 2) were significantly shorter

than those displayed by males implanted in the anterior hypothalamus and preoptic regions (PM+HAM).

Males (N=5) implanted in the region of the nucleus hypothalamicus posterior medialis (HPM) displayed significantly shorter durations of nest soliciting (Mann-Whitney U test, two-tailed, P < 0.05) than males implanted in the anterior hypothalamus and preoptic regions (PM+HAM). No other courtship behaviour was recorded from HPM males. A group of males (N=4) implanted in the palaeostriatum primitivum (PAL.P) with testosterone propionate showed no response. A further group (N=5) implanted with cholesterol in the region of the nucleus hypothalamicus anterior medialis also gave no response.

These results indicate that an area incorporating the anterior hypothalamus and preoptic regions of castrated male doves is directly sensitive to testosterone and that this sensitive area is closely associated with systems controlling courtship. At present, the low levels of courtship obtained from males implanted in the neostriatum intermediale and in the region of the nucleus hypothalamicus posterior medialis would seem to be the result of diffusion of hormone to the sensitive area. The androgensensitive area described here corresponds well with the neural area from which Åkerman¹⁶ obtained the most intense responses of bowing and nest demonstration by means of electrical stimulation from the pigeon. The neuro-anatomical representations of the androgen-sensitive systems associated with courtship in the male dove and fowl7, however, clearly differ.

Continuous Recording of Bird Nesting Visits using Radioactive **Tagging**

In view of the successful application of radioactive tagging in entomology in Central Africa, I have investigated the potentiality of the method as a tagging technique in ornithology. Because the detection range of small amounts of radioactive material is only of the order of feet, the method requires the close proximity of the labelled bird and the radiation detector. It was decided to use the method to obtain data on the bird's nesting visits, and the tests not only demonstrated the potentiality of the method but also provided useful data on behaviour. search of the literature revealed that Barbour¹ made similar studies on the prairie vole (Microtus ochrogaster). Barbour used cobalt-60 as the radioactive tagging material, and the signal from the radiation detector was recorded on a tape recorder. Griffin² has given a thorough discussion on the maximum permissible dose rate to be used for tagging animals under natural conditions, and mentions, without going into detail, an experiment on the semipalmated plover Charadrius semipalmatus.

In this work, I used short lengths of small diameter wire, consisting of tantalum-182 sheathed in platinum. Tantalum-182 has a half-life of 115 days. The lengths are fixed to the usual aluminium bird rings with a suitable adhesive. By using rings with two strengths of radioactive label-one is usually twice the length of the otherit is possible to distinguish between the two parent birds. The radioactive strength of the label is governed by the maximum distance at which it is required to detect the bird compatible with minimization of the health hazard to the bird. In the tests described here, pieces of wire 1 mm in length (100 μ c.) were used for the "strong" rings and 0.5 mm in length (50 μc.) for the weak rings. Measurement even of the weak source was possible at 6 ft. with a scintillation counter, so that the detector could be kept well away from the nest. Although the radiation hazard to the operator is negligible, the bird itself receives a considerable dose of radiation. For example, using a 100 µc. tag of tantalum-182 on Merops nubicoides, the gonads would initially be in a radiation field of about 100 mr./h and at the lenses of the eyes the field would be about 10 mr./h. By arranging the detector to be only 2 ft. from the nest, it would be possible to reduce the size of the radioactive label by a factor of ten.

Two facts about the use of radioactive labels of this size are very encouraging. Both species of birds used for the tests remained healthy for the period of observation and raised healthy broods. Recently, 12 months after the tests, both sexes of one species were seen to be alive and behaving normally. A careful check using tagging with radioactive labels of this size in entomology showed no significant decrease in longevity in caged tsetse

The radiation detector was linked to a portable ratemeter and recorder by 50 m of cable. Use of a 12 V lead acid accumulator allowed the ratemeter to operate continuously for 10 days without recharge. A pen and ink recorder with a chart speed of 6 in./h was found to provide adequate time resolution to measure the frequency and duration of visits. Using the standard chart length-100 ft.—it was possible to obtain a continuous record of the presence or absence of either bird over a period of

The first experiment with this technique was with the white-flanked flycatcher (Batis molitor). The nest was located 5 ft. above the ground and it was possible to leave the radiation detector on the ground directly below the nest. Both parents were caught and ringed a few days before the eggs hatched, so that data were obtained on both brooding of eggs and feeding of young. Fig. 1A shows a typical recorder trace for Batis molitor with

characteristic frequent visits to the nest. In order to obtain an exact departure time, the two young were ringed with radioactive tags of low strength shortly

before their expected departure.

The second experiment was with a tunnel nesting species, the carmine bee-eater (Merops nubicoides). Observations of nesting activity by visual methods are complicated because: (a) visits to the nest must be inferred from entries to and exits from the tunnel; (b) the species nests colonially and confusion frequently results during active periods at the colony; and (c) the sexes are alike. During a week of intensive study of the nesting behaviour of Merops nubicoides, a method was developed for catching birds from a particular nesting burrow. The parents were labelled with radioactive rings and, as before, one was tagged with a ring twice the strength of the other. The burrow selected for the test was 2 ft. below the top of the vertical river bank in which the colony was situated. The recording apparatus was in a hide on top of the bank and was linked by cable to the detector situated on the ground exactly over the nest chamber. The gamma radiation from 50 µc. of tantalum-182 was sufficiently energetic to reach the detector through 2 ft. of soil with adequate signal strength. A marked improvement was achieved, however, by making a short auger hole, large enough to pass the scintillation probe, the bottom of which was 1 ft. from the nest chamber. Data were obtained for a week of continuous recording and a typical part of the chart is shown in Fig. 1. The rather infrequent feeding visits may have been because there was only one chick in the nest. At the end of the week, the parents and young were collected to establish which sex had the strong label and which the weak one.

Information on both the duration and frequency of visits is available from the charts and an investigation of attentiveness at the nest has been made and will be published elsewhere. The analysis gives percentage incubating and brooding times and information on the role of the parents of each species in feeding and brooding during the nesting period. During the nesting period visual observations for periods of several hours were undertaken and these provide a valuable key to assist in interpreting the trace. Typical behaviour patternsfor example, feeding of the female by the male in Botis molitor-are confirmed by the recorded data. Roosting behaviour in the case of Merops nubicoides is easily investigated to establish whether only one parent stays in the nest at night.

Other possible applications of radioactive tagging in ornithology include the investigation of roosting

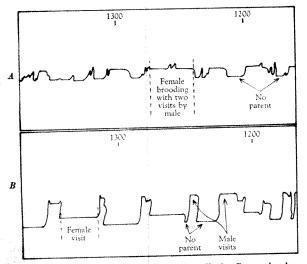

Fig. 1. A, White-flanked flycatcher (Batis molitor); B, carmine bee-eater (Merops nubicoides).

times and behaviour at communal roosts and heronries, and of the nesting behaviour of nocturnal species.

I acknowledge the close co-operation of Mr H. D. Jackson and Mr D. Solomon in this work.

Fourth Haemoglobin Type in Sheep

Three haemoglobin phenotypes accounted for by the existence of two alleles have been demonstrated in various breeds of sheep1-4. Animals studied have included those homozygous for haemoglobin A (Hb-A) or haemoglobin B (Hb-B) while others were heterozygous for these two haemoglobins. In 1963, a new haemoglobin type was reported in sheep carrying the Hb-A gene after they had been made anaemic by severe bleeding. A new type of haemoglobin (designated Hb-C) was later reported in sheep with experimental anaemias. Haemoglobin C completely replaced Hb-A in the severely anaemic animals. No such variant was detectable in sheep homozygous for Hb-B after severe loss of blood. This Hb-C is probably the same as Hb-N described by Brænd et al.7 in a highly anaemic lamb, and occurring rather commonly in Norwegian breeds of sheep8,8. Studies of the chemical structure of the previously mentioned ovine haemoglobins have shown that they differ in the non-alpha chains (Hb-A = $\alpha_2^A \beta_2^A$, Hb-B = $\alpha_2^A \beta_2^B$, Hb-C = $\alpha_2^A \beta_2^C$) (refs. 6, 10–12).

This communication describes the discovery of a new sheep haemoglobin type, designated haemoglobin D, which was found in three sheep during a survey of a native flock of approximately 500 adults. Fig. 1 shows a starch gel electrophoretic separation using tris-EDTA-boric acid buffer, pH 9·0; the haemoglobin bands were stained with benzidine. The samples for this electrophoresis were selected to demonstrate the relative mobilities of the various sheep haemoglobins (A, B, C, D, F). Haemoglobin D has the fastest electrophoretic mobility at pH 9·0, followed in decreasing mobility by Hb-A, Hb-F, Hb-B and Hb-C.

Table 1. HARMATOLOGICAL DATA OF SHEEP WITH Hb-D

Sheep	Erythrocytes (10°/mml.°)	Hb (g/100)	PCV (%)	Retic.	Haemog A	dobin (p B	ercent) D
G-157 G-261 G-301	7·62 8·91 10·67	$8.4 \\ 8.7 \\ 11.3$	29 33 39	2 1	50 50 50	30 40 36	20 10 14

Haemoglobin D was found only in those animals which seemed to carry the haemoglobin AB genes. The Hb-D band was 10-20 per cent of the total haemoglobin while that of the Hb-B band was between 30 per cent and 40 per cent. No changes were detectable in the quantity of the Hb-A band which constituted the remaining 50 per cent (Table 1). The results of the haematological studies of the sheep with Hb-D are given in Table 1. The data show that two animals (G-157 and G-261) were moderately anaemic, while the third (G-301) was haematologically The red blood cells of the three sheep were separated by centrifugation into populations of different mean ages by the method of Borun et al.13. There was no significant difference in the percentage of Hb-B and Hb-D in the young and old red blood cells. aforementioned sheep gave birth; one lamb was found to have Hb-B and the other Hb-AB. No Hb-D was detected in either lamb.

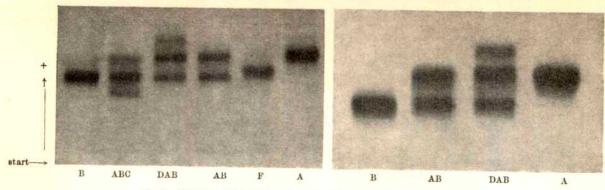

Fig. 1. Relative position of sheep haemoglobins; tris-EDTA-boric acid buffer, pH 9-0.

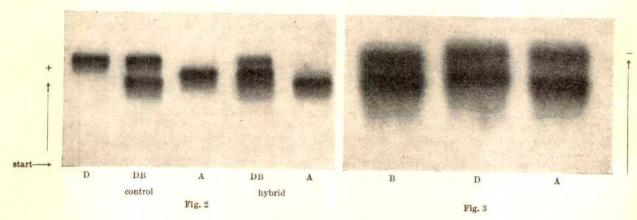

Fig. 2. Results of hybridization experiments of Hb-D with Hb-B.

Fig. 3. Electrophoretic separation of the peptide chains of Hb-D, Hb-A and Hb-B in acetate-phosphate-urea-hydrochloric acid buffer, pH 1-8.

In vitro hybridization experiments14,15 with haemoglobins A, B and D isolated by starch block electrophoresis indicated that Hb-D is an alpha chain variant (α⁰₂). Fig. 2 shows the results of such an experiment with Hb-B and Hb-D. A component with the relative mobility of Hb-A (α,β, is produced, indicating the association of the normal alpha chains of Hb-B $(\alpha_2^A \beta_2^B)$ with the normal beta chains of Hb-D $(\alpha_2^D \beta_2^A)$. The second hybrid haemoglobin (α β β) probably has the same net charge and therefore the same electrophoretic mobility as Hb-A. No hybrid haemoglobins were detectable in similar hybridization experiments with haemoglobins A and D in our experimental conditions.

Starch gel electrophoresis of isolated Hb-D in acetate, phosphate, urea and hydrochloric acid buffer¹⁶ (pH 1·8) revealed the presence of one sub-unit with a slightly faster mobility than the alpha-A chains, and another sub-unit with a mobility indistinguishable from that of the corresponding sub-unit of Hb-A (Fig. 3). From these studies Hb-D seems to be composed of altered alpha chains $(\alpha_2^{\rm b})$, and similar beta chains as in Hb-A (Hb-D = α^D₂β^A₂). Sheep with the three haemoglobins A, B and D would be double heterozygotes for the alpha (α_2^A, α_2^D) and This would yield the following beta (β_2, β_2^8) chains. haemoglobins: Hb-A $(\alpha_2^A \beta_2^A)$; Hb-B $(\alpha_2^A \beta_2^B)$; Hb-D $(\alpha_2^D\beta_2^A)$; Hb-B/D $(\alpha_2^D\beta_2^B)$. This suggests that sheep heterozygous for the alpha chain variant, and homozygous for the beta-B chain variant, are erroneously identified as AB sheep because Hb-A and Hb-B/D probably have the same electrophoretic mobility. In sheep heterozygous for the alpha chain variant and homozygous for the beta-A chain, only Hb-A and Hb-D would be present. The results of this study, although somewhat

limited in the number of animals studied, indicate the existence of a fourth haemoglobin allele, HbD, in sheep.

Shell Movements of a Wood **Boring Bivalve**

Some bivalves of the super-family Adesmacea are known to penetrate wood by means of mechanical action of the shell valves. The process has been described by various authors, the most comprehensive account being that of Miller¹ for Teredo. Although rocking movements of the shell valves about a dorso-ventral axis are known to be important in penetration of this substratum2, there seem to be no records for any wood boring bivalve of the type and frequency of the shell movements involved.

We have recorded and filmed the shell movements of Xylophaga dorsalis Turton. Adult specimens of this bivalve were obtained from laminated timber test panels exposed at Keppel Pier, Millport, on August 9, 1966, and recovered in August 1967. Xylophaga was found readily boring through such laminated panels, unlike certain species of Teredo whose burrows do not extend through the laminations. By careful separation of the individual laminae specimens of Xylophaga were exposed without any damage and with minimum interference to the animal in the burrow. Specimens removed from the burrows and replaced in smooth cylindrical holes drilled in pieces of cork soaked in sea water were also found to resume boring activity. Records of movements of the shell valves were obtained on a pen recorder (E. and M. Instrument Co. Inc., 'Physiograph'), using an isometric myograph, attached by fine thread to the posterior wing of one valve of the shell.

During several days, when the animals were kept and observed in a continuous flow of sea water, the shell movements chiefly consisted of irregularly spaced periods of vigorous activity (Fig. 1) interspersed with periods of relative inactivity, during which only slight or infrequent larger movements were made. Stoppage of water flow resulted in a slowing down or even cessation of activity

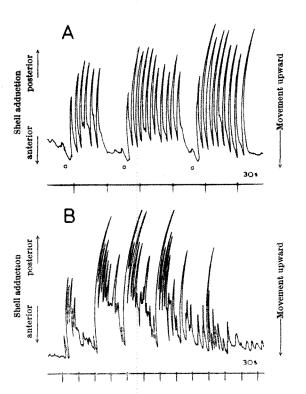

Fig. 1. Two extracts from a recording of the activity of the wood boring bivalve Xylophaga dorsalis. A. Three cycles of boring activity comprising six, eleven and nine rocking movements of the shell valves respectively, caused by successive contraction of the posterior and anterior adductor muscles. Before each group of rocking movements the foot is first relaxed, causing upward movement of the shell in the burrow (a) and the shell is then immediately drawn downwards to the base of the burrow. B. One complete group of boring cycles showing the variation in number and strength of the rocking movements involved.

which was, however, rapidly resumed when the water flew was restarted. During the periods of activity characteristic shell movements were recorded which differed from any hitherto recorded from bivalves, and which are clearly associated with enlargement of the burrow. The shell is drawn towards the blind end of the burrow by the contraction of the pedal retractor muscles, the sole of the foot being attached to the walls of the burrow by mucus secretion. The shell valves then rock about a dorso-ventral axis by the alternate contraction of, first, the posterior and then the anterior adductor muscles (Fig. 1B), the umbones and ventral articular knobs forming a fulcrum for this During the contraction of the posterior movement. adductor muscles the denticulate ridges sculpturing the anterior outer faces of the shell valves are drawn across the walls of the burrow with an effective abrasive action. Considerable variation was recorded in the number of alternate contractions of the adductor muscles comprising each boring cycle as well as in the strength of adduction of the shell valves. Small rotatory movements of the animal were also evident (not shown in the recordings) occurring between the series of rocking movements.

These recordings illustrate the specialization of the movements involved in boring into wood in the Adesmacea. Each series of rocking movements is apparently homologous to the boring cycle of the less specialized Pholadidae, which in turn has characteristics in common with the digging cycle of those species which burrow into soft substratas. The movements recorded therefore fully support the view that rock boring in this group has evolved as a specialization of a deep-burrowing habit4.

The mechanisms of boring in Xylophaga and the rela-

tionships of these to burrowing and boring in other bivalves will be reported in greater detail elsewhere. This work was carried out during the tenure of a Royal Society and Nuffield Foundation Commonwealth Bursary held by one of us (N. B. N.).

Virus-like Particles in a Weed Mould growing on Mushroom Trays

During investigations of virus diseases of the cultivated mushroom, Agaricus bisporus (Lange) Sing., samples were collected of a species of Plicaria which is probably similar to Plicaria fulva described by Schneider¹ [synonym Peziza atrovinosa Cooke and Gerard]. This fungus is considered to be the perfect stage of Botrytis crystallina (Bon.) Sacc.², the brown mould. Apothecia of P. fulva, collected from various mushroom farms, were tested for the presence of virus particles to investigate the possible role of this weed mould in the spread of viruses of cultivated muchrooms.

Purification was carried out by a method found satisfactory for mushroom viruses3: about 10 g of apothecia was homogenized for 2 min in a Waring blender with 30 ml. of 0.033 molar phosphate buffer containing 0.1 per cent thioglycollic acid, adjusted to pH 6.8. Samples of

the homogenate (50 ml.) were subjected to ultrasonic treatment with a Kerry Vibrason cell disruptor (probe diameter 0.9 cm, output 50 W) for 10 min⁴. During the treatment the fungal suspension was kept at 4° C. The crude homogenate was then clarified by a method based on that of Kitano et al.5. To 1 volume of homogenate was added an equal volume of 2.5 molar potassium phosphate buffer pH 6.8 and 0.8 volumes of a mixture of 2-butoxyethanol and 2-ethoxyethanol (1:2). After mixing the components gently and centrifuging at 1,000g for 5 min the gelatinous interphase was resuspended in 10 ml. of 0.033 molar phosphate buffer pH 6.8. After centrifugation at 5,000g for 10 min the supernatant was centrifuged at 105,000g for 60 min. Resuspension of the pellet in 0.25 ml. of phosphate buffer was followed by centrifugation at 5,000g for 10 min to give a preparation which was negatively stained with a drop of 2 per cent phosphotungstic acid adjusted to pH 5.5 and examined with a Siemens Elmiskop 1 electron microscope.

Altogether nine samples of P. fulva apothecia of various origins were studied. Some of them contained a few spherical particles, diameter 25 mμ, resembling mushroom virus 1 (refs. 3 and 6). In five samples, however, there were rigid rods, strikingly virus-like (Fig. 1). They had a clear central cavity and tended to aggregate. Most particles were 350 × 17 mµ in size. The apothecia of the samples with rods did not differ visibly from those without. No cytological observations were made, however.

Their morphology and their occurrence only in some samples and even then in varying concentrations suggest that the particles represent a virus. Infection experiments could not be carried out because it has not yet been possible to cultivate apothecia of P. fulva1.

In some samples of cultivated mushrooms similar rodshaped particles were observed although in minute concentrations (Fig. 2). Attempts are being made to infect cultivated mushrooms with the rods. The known mushroom viruses are easily transmitted by hyphal anastomosis. but inoculation of mushroom cultures with cell-free virus preparations has been successful only in a few cases3.6. For the rod-shaped virus-like particles this might be even more difficult, for their concentration in cultivated mushrooms is much lower.

Inoculation of purified preparations from apothecia of P. fulva, containing large numbers of rods, onto Nicotiana glutinosa L., N. tabacum L. var. White Burley, Phaseolus

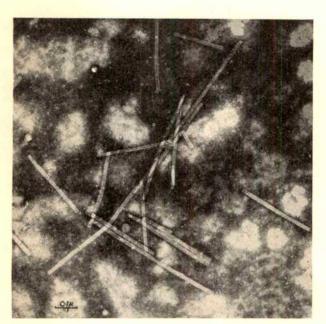

Fig. 1. Rod-shaped particles from Plicaria fulva R. Schneider,

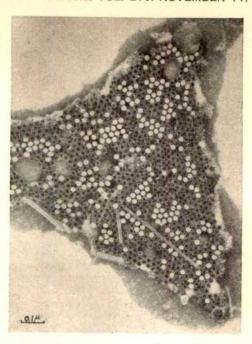

Fig. 2. Some rod-shaped particles among 'spherical' mushroom virus from Agaricus bisporus (Lange) Sing.

vulgaris L. var. Bataaf, Gomphrena globosa L. and Chenopodium amaranticolor Coste and Reyn did not induce any visible reaction in these plants, thus eliminating the possibility of contamination of the fungal material with a strain of tobacco mosaic virus.

Electron micrographs were prepared by the Service Institute for Applied Mechanics and Technical Physics in Agriculture, Wageningen.

Morphogenesis of Shoot Primordia in Cultured Stem Tissue of a Garden Rose

Skoog and Miller1 reported that auxin and kinetin can be used in growth media for tobacco stem tissue cultures to control the morphogenesis of shoots and roots. Other authors have reported on shoot formation in tissue cultures of other species, for example, convolvulus2,3 and endive4.

A climbing hybrid tea rose, tentatively identified as 'The Doctor', which grows in a border of Twyford Laboratories in London, has served as the source of many tissue cultures grown in these laboratories. A fast growing callus can be started and maintained on a 15 per cent coconut milk medium containing 2,4-dichlorophenoxyacetic acid (2,4-D) at concentrations from 0.05 to 5.0 mg/l. For some time I used such callus for studies on the effect of auxin and kinetin, but no organogenesis was ever observed. In August 1965, however, explants of stem were inoculated onto synthetic media containing 2 mg/l. of naphthyl acetic acid (NAA) and 0.2 mg/l. kinetin or

0.2 mg/l. NAA and 2 mg/l. kinetin. The callus which developed was cultured on media with 1 mg/l. of kinetin or 1 mg/l. kinetin plus 1 g/l. of soya peptone. Three cultures of those treated developed one or more shoot primordia. They were subcultured a number of times onto various media in an attempt to make the primordia develop into normal looking shoots, but this has failed, although one culture has a bud with recognizable trifoliate leaves. In general, however, the primordia consist of clusters of small petaloid organs (1-2 mm in diameter) either colourless or green. Although there has been little development of the primordia, their proliferation has been considerable: for example, from one culture originally with one primordium there are now (after five subcultures) twenty cultures, each with several primordia. Table 1 shows the history of this line of cultures with the media

Table 1. HISTORY OF SUBCULTURES OF ROSE CALLUS WITH SHOOT PRIMORDIA

subculture	mg/l.)	with primordia
Explant	2 NAA 0 2 K	None
1	1 K	1
2	0-1 IAA	1
3	0-5 NAA	2
4	0.5 NAA or 0.5 NAA+1 K	7
5	0·5 NAA 0·2 K 20 GA	20

IAA, β-indolylacetic acid; GA, gibberellic acid; K, kinetin.

The medium given last, with 20 mg/l. of gibberellic acid, is the most successful with regard to both proliferation and development of the primordia.

It has been comparatively easy to keep the cultures producing a primordia despite changes of medium, and it can be concluded that the constitution of the culture is fairly stable. Why then is it so difficult to produce such a culture? It seems probable that the development of such a culture requires conditions which rarely occur, but which sometimes arise in the interaction between explant cells and the medium. An interesting question is whether a primordium, once present, can influence the culture to produce further primordia. One approach to this problem would be to culture shoot tips or axillary buds and see if a callus can be obtained with desired properties.

Photosynthetic Oxygen Evolution by Isolated Chloroplasts in the Presence of Carbon Cycle Intermediates

RECENTLY developed techniques have led to the isolation of intact chloroplasts which will assimilate carbon dioxide at rates approaching those achieved by the intact plant¹⁻⁶. This has made it possible to measure the associated oxygen evolution, polarographically, in aerobic conditions? Normally, oxygen evolution parallels carbon dioxide fixation^{7,8}. On illumination, both start slowly and accelerate gradually until a maximum rate is reached after several minutes. This induction phase is thought to reflect corresponding changes in the concentration of carbon cycle intermediates as these increase autocatalytically to a steady state level^{2-4,7-11}. If 3-phosphoglycerate (PGA) is provided as a substrate the initial lag is virtually

eliminated? and the kinetics then approximate to those observed in the Hill reaction¹² in which an artificial hydrogen acceptor reacts more directly with the photochemical system. This was held? to be consistent with the view¹³ that the 3-phosphoglycerate is the immediate precursor of the hydrogen acceptor (1,3-diphosphoglycerate) in the carbon cycle. If this is correct, it would follow that the oxygen evolution observed when PGA is added as a substrate? should not be dependent on carbon dioxide-bicarbonate (Fig. 1). Conversely, any stimulation of oxygen evolution by triose phosphate should cease in the absence of carbon dioxide. Experiments which substantiate these conclusions are reported here.

Chloroplasts, with intact envelopes, were isolated from spinach as before^{1,8,11} but in a solution of sorbitol (0.33 molar), magnesium chloride (0.1 per cent w/v) and sodium pyrophosphate^{5,8,11,14} (0.01 molar) at pH 6.5. They were then resuspended and assayed in a similar solution except that the pyrophosphate was replaced by Hepes solutions (0.05 molar) at pH 7.6, the magnesium chloride was 0.601 molar and a small quantity of manganese chloride (0.002 molar) and EDTA (0.002 molar) were also added. Oxygen evolution was measured at 20° C in rapidly stirred mixtures using two Rank electrodes' and a twin channel recorder. High intensity white light (about 6,000 ft. candles) passed through 15 cm of water as a heat filter, was provided by two quartz-iodine slide-projectors. Illumination was started after 4 min of dark equilibration.

Fig. 2 shows induction phenomena in oxygen evolution by isolated chloroplasts in reaction mixtures containing no added orthophosphate and in which the inorganic phosphate requirement^{5,6,8,11,14} is met by small quantities

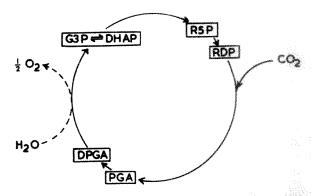

Fig. 1. In the photosynthetic carbon cycle¹⁸, reduction of added PGA could occur in the absence of carbon dioxide. Conversely, triose phosphates such as DHAP and G3P would normally be converted to PGA only in the presence of carbon dioxide.

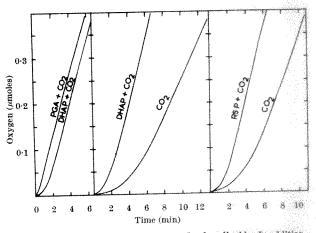

Fig. 2. Oxygen evolution in the presence of carbon dioxide. In addition to chloroplasts (100 μg of chlorophyl) in resuspending medium (see text) each mixture (1-5 ml.) contained bicarbonate (15 μ moles) and 5 μ moles of PGA, R5P and DHAP as indicated.

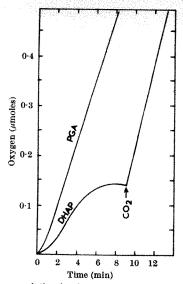

Fig. 3. Oxygen evolution in the absence of added carbon dioxide. Mixtures as for Fig. 2 but initially without bicarbonate which was later added as indicated (15 μ moles) to the mixture containing DHAP. Similar results were obtained when G3P was substituted for DHAP.

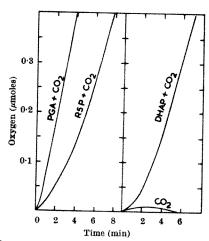

Fig. 4. Suppression of oxygen evolution by high orthophosphate in the presence of carbon dioxide alone. In addition to chloroplasts (200 μg of chlorophyll) in resuspending medium (see text) each mixture contained bicarbonate (15 μ moles), sodium orthophosphate (10 μ moles, pH 7·6) and 5 μ moles of PGA, R5P and DHAP as indicated.

of pyrophosphate carried over from the grinding medium. The traces are presented in pairs which were recorded simultaneously to minimize such differences as may develop as the chloroplasts "age" after separation from the parent tissue. It can be seen that there was a lag of 5-6 min with carbon dioxide as the sole added substrate, but that this could be considerably shortened by the addition of ribose-5-phosphate (R5P) or dihydroxyacetone With PGA, the lag was barely phosphate (DHAP). discernible (compare ref. 7). Each reaction mixture represented in Fig. 2 contained added bicarbonate. When the bicarbonate was omitted (Fig. 3) the kinetics of oxygen evolution in the presence of PGA were essentially unchanged. With DHAP (or G3P), however, oxygen evolution started but soon ceased, presumably as the supply of endogenous carbon dioxide became exhausted. At this point evolution could be restarted by the addition of bicarbonate. Similar results have been obtained with mixtures containing R5P (ref. 7) and also in the absence of added substrate⁸. It follows that, although this result shows that DHAP, unlike PGA, cannot sustain oxygen evolution in the absence of added bicarbonate, it does not provide definitive evidence of an actual contribution of

DHAP to oxygen evolution. Such evidence may be obtained by taking advantage of the fact that the lags vary according to the orthophosphate concentrations, 11, 14. Fig. 4 shows the responses obtained in reaction mixtures containing 10 µmoles of added orthophosphate (6.6×10^{-3}) molar). Oxygen evolution in the presence of PGA started as before without an appreciable lag. With R5P and DHAP the lags were marginally longer. With carbon dioxide alone the lag was so prolonged (compare refs. 8, 11 and 14) that oxygen evolution was almost entirely suppressed during the period of measurement. The mechanism of suppression is still uncertain but orthophosphate is a known competitive inhibitor of ribulose diphosphate carboxylase¹⁵. As such it would not be expected to affect the oxygen evolution observed in the presence of substrate concentrations of 3PGA, and its effect on carbon dioxide fixation might well be reversed by those intermediates¹³ which could facilitate a build-up of ribulose diphosphate. This suppression, by high orthophosphate, of the oxygen evolution obtained when carbon dioxide is the only added substrate^{8,11} was used to advantage in the experiment illustrated in Fig. 5. In the same way as before, evolution was allowed to start in the absence of added bicarbonate. When net evolution had ceased, 10 µmoles of orthophosphate was added to each mixture, followed by carbon dioxide and DHAP as indicated. In these conditions it can be seen that evolution was not resumed until both DHAP and carbon dioxide were present. Conversely, the fact that the oxygen evolution which occurs in the presence of added PGA' will start and continue in mixtures containing very little carbon dioxide is again evident in Fig. 6. Illumination was started in the absence of added

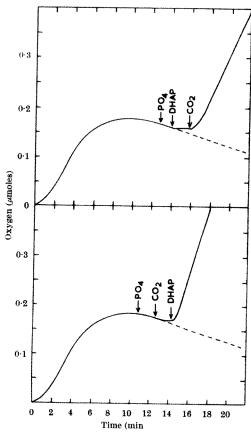

Fig. 5. Carbon dioxide dependent oxygen evolution induced by DHAP. Initially each mixture contained only chloroplasts (100 µg of chlorophyll) in resuspending medium (see text). When net evolution had ceased, sufficient orthophosphate (Fig. 4) was added to suppress the oxygen evolution which would otherwise have followed the addition of bicarbonate (Fig. 6). Oxygen evolution was then only resumed when both DHAP (5 µmoles) and bicarbonate (15 µmoles) were added. Similar results were obtained when G3P was substituted for DHAP.

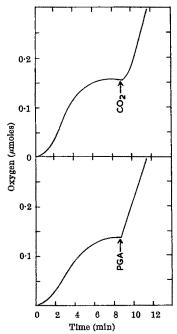

Fig. 6. Oxygen evolution in the presence of PGA in carbon dioxide deficient mixtures. Initially each mixture contained only chloroplasts (100 µg of chlorophyll) in resuspending medium (see text). When net evolution had ceased it could be restarted either by bicarbonate (15 μmoles) or PGA (5 μmoles).

bicarbonate. When net evolution had ceased it could then be restarted either by the addition of carbon dioxide-bicarbonate (compare ref. 7) or PGA alone.

The results suggest that 3-phosphoglycerate can replace carbon dioxide as a substrate in initiating oxygen evolution whereas the triose phosphates are only effective when carbon dioxide is also present. This is consistent with the Benson-Calvin cycle¹³ (Fig. 1) and provides further evidence (see also refs. 16 and 17) of its operation in isolated chloroplasts.

MICROBIOLOGY

Isolation in Pure Culture of Human Oral Organisms capable of producing Neuraminidase

Previous reports¹⁻³ have indicated that most, if not all, of the carbohydrate components of the mixture of glycoproteins as they exist as saliva in the human mouth are labile and are released by induced enzymes of bacterial origin. One of these enzymes—neuraminidase or sialidase is of particular interest because the loss of sialic acid from saliva causes some of the glycoprotein components to precipitate out of solution, and this reaction may be an important factor responsible for the formation of dental plaque on the teeth. The loss of the other carbohydrate components (three hexoses, two hexosamines and fucose) must influence the calcium binding capacities of the residual proteins and this reaction must also be of significance in the formation of both dental plaque and calculus. Dental plaque has already been shown to bind more calcium than does an equivalent amount of salivary protein. Neuraminidase is also of interest in other fields, where it has been shown, for example, to be the receptor destroying enzyme of myxovirus to erythrocytes and its presence could also be responsible for markedly changing the physical characteristics of mucins throughout the body during certain disease processes.

Few bacteria, particularly those of the genera usually found in the mouth, have as yet been recognized in pure culture as able to produce neuraminidase. enzyme and the other equivalent extracellular glycosidases, however, are regularly produced by the mixed oral flora as it exists in saliva and have been found in the mouths of everyone tested to date3.

Bacterial neuraminidase has been shown to be an induced enzyme which requires the necessary substrate together with other essential materials in trace quantities for its effective elaboration^{6,7}. Because the mixed oral flora very obviously thrive in the mouth and collectively produce neuraminidase, saliva itself seemed to be an extremely suitable medium containing all the necessary ingredients for its elaboration.

Saliva was collected from members of the laboratory staff and from dental students by paraffin wax stimulation. All samples were pooled within 15 min of collection and were placed in a water bath at 60° C for 1 h. This procedure was found both to sterilize the saliva and to retain most of its sialic acid in a bound form. Before the saliva could be used to prepare saliva-agar plates, however, it was found to be essential to remove the contaminating wax because this formed an impervious and almost undetectable layer on the surface of the solid culture medium and made effective inoculation with a standard bacteriological loop almost impossible. The wax particles were removed by suction from the surface of cooled (0°-4° C) and centrifuged (1,000 RCF, 10 min) samples of the saliva using a Pasteur pipette. A fungicide ('Nystatin'. 2,000 U/ml. of saliva) was then added and the saliva reheated at 60° C for a further hour, after which 15 per cent by volume of 5-8 per cent agar (60° C) was added. Saliva-agar plates prepared from this material by this method were found to be bacteriologically sterile. When these plates were inoculated with freshly collected human saliva and incubated overnight at 37° C, many bacterial colonies were produced both aerobically and in an atmosphere of 95 per cent nitrogen and 5 per cent carbon dioxide. Most of the organisms were found to be Gram positive cocci, but some Gram negative cocci and many Gram positive and negative rods were also present. The number of colonies growing on this medium was found to be of the same order as on blood-agar under the same conditions of growth. The individual colonies of bacteria could be subcultured onto further saliva-agar plates and,

when samples of these pure cultures were added to 1 ml. of sterile saliva and incubated overnight, they were found to remove most of the sialic acid, as measured by the method of Warren⁸.

It therefore seems that those organisms capable of growing on sterile saliva-agar are also capable of producing neuraminidase. This is confirmed by further subculturing with sterile liquid saliva when the specific loss of sialic acid can be easily assayed by chemical methods. The marked loss in reactivity of the incubated saliva to the periodic acid-Schiff reaction⁹ indicated that at least some of the other glycoprotein carbohydrates had also been lost, but at the present time this has been confirmed for fucose only. The most surprising aspect of this work from our point of view is that most of the oral bacteria, of which there are many different genera present10, seem to be able to produce neuraminidase and presumably the other complementary extracellular glycosidases when presented with an environment suitable for their elab-

A more precise identification of the organisms involved and an attempt to produce a more easily available synthetic medium for demonstrating the presence of these enzymes is now being undertaken.

DNA Base Composition of Toxoplasma gondii grown in vivo

THE nature and taxonomy of the parasite Toxoplasma gondii are uncertain. A relationship to Besnoitia and Sarcocystis has been suggested and classification with Sporozoa has been proposed. The problems have been discussed in detail4.

Phylogenetic relations of protozoa may be reflected in their DNA base compositions, and information on DNA base composition may be particularly useful where relationships among Sporozoa are being examined because of their apparently polyphyletic origins4. This study was undertaken to provide such information for Toxoplasma.

Toxoplasma (RH strain) were obtained from albino mice infected by the method of Blaker⁶. Dying animals were killed by spinal dislocation, and peritoneal exudates collected in heparinized buffered saline (0.5 mg of heparin [75 USP units]/ml. of 0·1 molar phosphate buffer, pH 7·0, made isotonic by the addition of 3.5 g of sodium chloride/l.). Cells were washed once in the same buffer, resuspended in saline-EDTA7 and leucocytes removed by filtration8 through a sintered glass filter (Corning, medium coarse porosity, 15-25µ maximum pore size; a medium porosity filter, $10-15\mu$, did not allow Toxoplasma to pass). The procedure also removes some Toxoplasma but has no effect on

the viability of parasites as shown by mouse inoculation. Microscopic inspection of filtrates showed Toxoplasma and very few erythrocytes; leucocytes were rarely observed. Cells were lysed with sodium dodecyl sulphate and the DNA partially purified7. The DNA base composition was determined by density gradient centrifugation.

The DNA base compositions of organisms representing several subclasses of protozoa have been reported and most cluster in groups which reflect their taxonomic position: Phytomastigophora^{5,10,11} range from 66 to 58 per cent guanine plus cytosine (*Euglena*, 46 per cent); Zoomastigophora^{5,12,13}, 59–50 per cent; Holotricha^{5,10,14}, 35-29 per cent (Tetrahymena patula, 22 per cent); and Rhizopoda⁵, 22 per cent.

DNA from Toxoplasma has a density of 1.712 g/cm³ (Escherichia coli DNA taken as primary reference, 1.710 g/cm3), and a guanine plus cytosine content of about 53 per cent. This value is close to that reported 15 for the Haemosporidium, Anaplasma (about 50 per cent guanine plus cytosine), and also falls within the range of values reported for flagellates. A conclusive statement on the position of Toxoplasma cannot be made, however, until additional data for the Sporozoa become available for comparison.

Uncoating and Development of Vaccinia Virus in Miniature Cells induced with an Extract from Marine Algae

Dissection of individual cells by microsurgery into nucleate and anucleate cytoplasm provides an effective means for the delineation of nuclear participation during virus infection¹. Recently, we described² the formation of aberrant cells and mitotic anomalies after treatment of tissue cultures with a biologically active concentrate derived from marine algae. The induced abnormalities included mixed populations of micronucleate and miniature cells. The sequence of their formation was recorded by time-lapse, phase cinematography. Micronucleation presumably occurred by a process similar to that obtained with colchicine3. Following metaphase, miniature cells were formed by multiple cytokinesis. Three to eight or more discrete daughter cells were usually produced from each mother cell thus affected. Each miniature cell contained one or more nuclear-like structures and hence only part of the total chromosomal complement of the mother cell. Occasionally, cytoplasmic fragments without nuclear material were noted which were, however, usually shortlived in our experimental conditions. This communication describes the development of vaccinia virus in preformed populations of miniature cells.

The following procedures were used. Stock cultures of the McCoy cell line4 were trypsinized and suspended in 30 ml. of nutrient medium (mixture 199 supplemented with $10\,\mathrm{per}$ cent calf serum, $0{\cdot}1$ mg streptomycin/ml. and $100\,\upsilon$ of penicillin/ml.) at a concentration of 300,000 cells/ml. in each 300 ml. flask. A lyophilized preparation of algal extract was added at a predetermined final concentration as described elsewhere². Cultures were placed in a rotary shaker water bath at 37° C for about 22 h. Samples (2 ml.) were transferred to Leighton tubes with coverslips. After incubation for 6 h, unattached cells and debris were decanted and nutrient medium (without algal extract and only 1 per cent calf serum) was replaced for 16 h. Coverslips were stained with acridine orange and examined by fluorescence microscopy5. In most experiments, miniature cells, micronucleate cells and arrested metaphase configurations represented approximately 30 per cent, 40 per cent and 5 per cent of the total cell population, respectively. The remaining 25 per cent were polykaryons and giant cells with deformed nuclei. Only occasionally were "normal" mononucleate cells seen.

Such atypical cell populations on coverslips were challenged with a large dose of vaccinia virus (strain WR). Preparations were examined 4-6 h after challenge for cytochemical evidence of "factory areas" (viral inclusions) as recently described. Within the limits of resolution of the cytochemical staining technique used, typical "factory areas" associated with vaccinia development were noted in most of the micronucleate and miniature cells. The relatively few cells which did not contain visible inclusions were either too small or could have been in metaphase arrest at the time of virus challenge and hence did not synthesize appreciable amounts of messenger RNA for 'uncoating'' proteins.

Joklik, has suggested that the "uncoating" of vaccinia virus is mediated by proteins coded by the host cell genome. In view of the varied and incomplete chromosome composition of each miniature cell, our observations suggest that the "uncoating" of vaccinia is not dependent on a specific segment of the host cell genome, although duplication of gene function on different chromosomes cannot be discounted at this time. Rather, our findings complement recent biochemical observations concerned with the synthesis of messenger RNA by the "coated" viral genome10.

This investigation was supported in part by the US Office of Naval Research.

BIOCHEMISTRY

Amino-acids and Amino-sugars in Calcified Tissues of Portunid Crabs

THE different parts of the exoskeleton of portunid crabs show a wide range of hardness and rigidity. The most rigid structure is the dactylus of the chela; most flexible and soft are the unmineralized joints between the limbs. The propodus, the carapace and the pleopods represent intermediate stages of rigidity. Because the extent of mineralization largely determines the flexibility and hardness of the exoskeleton we were interested to identify the important factors in this calcification process.

Previous work on mineralization in biological systems¹⁻⁷ has shown that the proteinaceous matrix in calcified tissues provides a set of very specific templates. Most essential in nucleating a mineral phase seems to be the availability of free carboxyl and amino groups provided by certain acidic and basic amino-acids. In the light of these results, we decided to determine the amino-acid and amino-sugar composition of representative regions in the exoskeleton and to relate these data to the calcification phenomena.

The animals selected were four specimens of Callinectes sapidus, one of Ovalipes ocellatus and one of Carcinilles maenas, all intermoult males. The regions sampled were the soft uncalcified joint membrane between the carpus and merus of the cheliped, the flexible paddle of the pleopod, the cardiac and gastric regions of the carapace and the propodus and dactylus of the cheliped. samples were freed of extraneous tissues and subjected to decalcification, hydrolysis and ion exchange chromatography8. Data on calcium, magnesium and strontium obtained by atomic absorption spectrophotometry, and on phosphate by colorimetry 10 were used as a measure of the degree of calcification of the individual organic matrix. The analytical results are summarized in Tables 1 and 2.

About 80 per cent of the weight of the samples could be accounted for after the chemical analysis if the inorganic salts are assumed to be carbonates and glucosamine to be an acetylglucosamine polymer. The missing portion partly represents humin and partly water; chitin is known to retain up to 10 per cent water even when dried to constant weight at 105° C (ref. 11).

The inter-relationships within and between the aminoacids, the amino-sugars and calcium were explored using factor analysis^{12,13}. This technique showed that 83 per cent of the total variance of the data was explained by only four groups of covariant compounds. A covariant group consisting of aspartic acid, tyrosine, serine, phenylalanine, glycine and threonine was strongly negatively correlated with a group consisting of lysine, proline, methionine, calcium and the ratio of the amino-sugars to total protein. A third group consisting of glutamic acid, valine, alanine, leucine and isoleucine was independent of the first two groups and a fourth group, similarly independent, consisted of arginine, histidine and hydroxylysine.

We believe that the association of the first two groups is related to the calcification process. For the independent group consisting of glutamic acid and isoleucine, although the pleopod, propodus and carapace contain increasing quantities of these amino-acids, different individuals have different relative amounts, as indicated in Fig. 1. Because of the difference in individuals, it seems most likely to be an environmental factor (for example, water temperature, pH, Eh, salinity or diet).

The increase in lysine and OH-lysine with progressing calcification agrees with the idea 1-3 that both amino-acids may provide nucleation sites for crystal growth. Inasmuch as chitin may also contain free amino groups11,14, the higher yields of glucosamine in the most mineralized regions of the exoskeleton may also be linked to calcification. Should dicarboxylic acids be essential in pro-

Crustacean cuticles are hardened by both tanning and mineralization processes. Usually an increase in tanning is accompanied by a reduction in mineral deposition and vice versa. Thus at least two distinct protein matrices are contained in the rigid structures of the exoskeleton. This phenomenon is analogous to the occurrence of mineralized proteins and the periostracum in molluse shells. A study of the amino-acid composition in tanned proteins of gastropods and cephalopods is helpful in the interpretation of the first covariant group consisting of aspartic acid, threonine, serine, glycine, tyrosine and phenylalanine. Essentially, the same amino-acids characterize the periostracum of these two classes of molluses15. This similarity is further underlined by the great abundance of amino-sugars in the tanned shell proteins. The association of aspartic acid with the tanned proteins and of proline with the mineralized tissues does not necessarily imply that the former is not involved in the actual calcification process whereas the latter is. It may be that because of processes unrelated to calcification, the mineralized tissues contain less aspartic acid and more proline than their tanned counterparts. The proportions

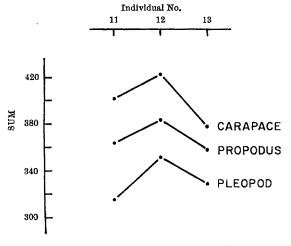

Fig. 1. SUM = glu + ala + val + leu + isoleu.

of tanning and mineralization vary from region to region as shown by representative values for the thickness of tanned and mineralized layers in Callinectes presented in Table 3. The strong negative correlation between the two groups of amino-acids is probably related to the changing ratio of tanned to mineralized cuticle in the various regions. The other two specimens included in this report, namely, Ovalipes ocellatus and Carcinus maenas, show essentially the same relationships we discussed before. The enrichment in lysine and amino-sugars with progressive calcification is even more pronounced than in Callinectes and may be a species characteristic.

The epicuticle and pigmented layers are tanned and calcified. The endo-cuticle is calcified.

Based on the amino-acid composition, the joint membrane differs in some aspects from the mineralized structures so far considered. For this reason, we excluded the data in our factor investigation. Particularly noteworthy is the abundance of proline and acidic, aromatic and basic amino-acids.

In relating the present data on mineralized tissues in portunid crabs with previous results largely inferred from electron micrographs¹⁶, we offer a tentative model of the calcification in this biological system. The cuticle of crustacea is a layered structure composed of minerals deposited in and between matted layers of chitin and protein fibrils. The fibrils chiefly lie in the plane of the layers, but some branch up and down to connect adjacent layers. The vertical fibrils line the walls of the numerous pore canals which run through the cuticle in a direction perpendicular to its surface. Organic materials form a diffuse matrix between the fibrils and in the pores. Mineralization proceeds along the fibrils but the resulting crystals are always small in size. Larger crystals are restricted to the interstices and lumen of the pore canals. It is inferred that the formation of multitudes of small mineral seeds in the fibrils represents the first crystallization stage. The deposition of large crystals comes later as nucleation sites in the matrix become gradually available. The larger size of the crystals in the second mineralization phase is simply a consequence of the fewer nucleation sites available along the organic templates. The individual layers are spaced further apart in the thick, highly calcified regions compared with the less mineralized regions. The proteinaceous matter is principally contained in the layers of matted fibrils, and consequently the most calcified regions have a greater proportion of mineral to

organic matter. This implies that with advancement of calcification, the organic matrix becomes a more effective template. In a sense, this is a duplication of what we observe in mollusc shells by going from primitive to very advanced forms¹⁵. With evolution, progressively less organic matrix is required for the nucleation of calcium carbonate. Whereas Nautilus, Haliotis or Mytilus may require a few per cent of organic matter for the deposition of their shell structure, some highly evolved gastropods such as Architectonica or Bulla get along with just 0.1 per

Effect of Age on the Amino-acids associated with Vascular Heparan and Chondroitin Sulphates

THREE principal groups of mucopolysaccharides-hyaluronic acid, heparan sulphates, and chondroitin sulphates exist in the ground substance of the human arterial wall. Their relative proportions change with age1,2, blood pressure² and arterial site³ in such a way as to suggest a possible relationship with atherosclerosis.

In connective tissue, mucopolysaccharides are firmly bound to protein. Muir4 implicated serine in the chondroitin sulphate-protein link, and recent work by Anderson. Hoffman and Meyer⁵ has substantiated this. Rodén et al. have shown that serine is not linked directly to the repeating disaccharide of chondroitin sulphate; in the vital region of the linkage, the regularly repeating disaccharide is broken into two galactose moieties and one xylose before the O-serine linkage.

Evidence of a different type of mucopolysaccharideprotein link has been advanced by Seno et al.7, who have also shown that the amino-acids associated with keratan sulphate after exhaustive proteolytic digestion vary according to the anatomical source of the material.

We have examined the amino-acids associated with mucopolysaccharides from the aortae of young and old human subjects. Whole aortae were obtained from four young (male, 20 ± 2 yr) and four old $(80\pm2$ yr) human cadavers at necropsy. The adventitia was removed and the tissue diced. Mucopolysaccharides were isolated by papain digestion² followed by dialysis and precipitation of the mucopolysaccharides with cetylpyridinium chlorides. The complex of mucopolysaccharides and cetylpyridinium chloride was dissociated in 2 molar sodium chloride, and the sodium-mucopolysaccharide was precipitated in 90 per cent ethanol. The isolated material was subjected to this procedure of papain digestion, cetylpyridinium chloride precipitation and final alcohol precipitation, three times. The purified mucopolysaccharides were then fractionated by increasing sodium chloride gradient elution from a 4.5×45 cm column of 'Dowex 1-C1' (ref. 9), with uronic acid assay10 of the column effluent.

Chromatograms obtained from young and old aortae are shown in Fig. 1. The average yield of mucopolysaccharide was 10.2 mg/g of dry tissue from young aortae and 5.9 mg/g from old aortae. Heparan sulphates left the column in 0.9 molar sodium chloride and chondroitin sulphates in 1.6 molar sodium chloride. uronic acid and heparan sulphates were reduced in old aortae. The quantities of hyaluronic acid isolated were too small for amino-acid studies. The heparan and chondroitin sulphates were isolated from the relevant column effluent fractions by dialysis and lyophilization.

Samples of mucopolysaccharide (2-4 mg) were hydrolysed in vacuum-sealed tubes (6 normal hydrochloric acid, 110° C, 22 h) and dried in vacuo over potassium hydroxide. Amino-acid analysis was carried out in an auto analyser. Samples for hexosamine assay11 were hydrolysed in 4 normal hydrochloric acid (100° C, 8 h).

Four amino-acids—serine, glycine, glutamic acid and aspartic acid-were found in each mucopolysaccharide sample, together with traces of threonine and alanine. Analyses of typical samples are shown in Table 1. The molar ratios Ser: Gly: Glu: Asp did not differ significantly in samples from young and old aortae, but there was a difference in the total amino-acid associated with the mucopolysaccharides from young and old aortae, there

being approximately twice as much amino-acid associated with heparan sulphates from old aortae, both on a weight for weight basis and in terms of mmoles of amino-acid/mole of hexosamine. This behaviour was similar in each of the four young and old heparan sulphate pairs examined, and was detectable, though in much lesser degree, in the chondroitin sulphate pairs.

Table 1. THE FOUR PRINCIPAL AMINO-ACIDS ASSOCIATED WITH HEPARAN AND CHONDROITIN SULPHATES

	Amino-acids (mmoles/mole of hexosamine)					
Sample	Ser	Gly	Glu	Asp		
Young CS	25·3	24·4	20·5	15·7		
Old CS	33·6	28·6	23·3	17·1		
Young HS	20·5	24·9	15·6	14·6		
Old HS	45·0	47·2	45·0	36·9		

HS, Heparan sulphates; CS, chondroitin sulphates; young, 19 yr old male; old, 82 yr old male.

Contamination with protein is unlikely to account for these results because the mucopolysaccharides were subjected to exhaustive proteolytic digestion and repeated precipitation; the mucopolysaccharide fractions isolated by column chromatography migrated as single homogeneous peaks on electrophoresis and in the ultracentrifuge; and only four amino-acids were present in measurable amounts in each mucopolysaccharide sample. digestion of the mucopolysaccharides with DNase did not affect the results, nor did fractionation of the mucopolysaccharides by the varying solubility of their cetylpyridinium chloride complexes in salt solutions9 instead of by ion-exchange column chromatography.

If, as seems likely, these amino-acids constitute minor peptide chains attached to the major mucopolysaccharide chains, the age effect may be caused by an increase in the amino-acids attached to the mucopolysaccharide chain, or by a decrease in the length of the mucopolysaccharide chain with increasing age. Preliminary studies in the ultracentrifuge reveal no striking difference in the molecular weights of young and old aortic mucopolysaccharides, and so it is likely that the change is in the minor amino-acid region of the molecule. The fact that the relative proportions of the four amino-acids remain constant (within the limits of experimental error) despite the increase in their total amount, with age, is slightly in favour of an increase in the number of aminoacid chains attached to the mucopolysaccharide molecules, rather than an increase in the length of the individual amino-acid chains, with increasing age.

One possible interpretation of these results is that they indicate an increasing degree of protein-mucopolysaccharide linkage with increasing age. Such a phenomenon could be of profound importance in influencing the molecular sieving effect of vascular ground substance, and may be of relevance to the development of arterial

Alkaline Phosphatase Relationships in Drosophila

ELECTROPHORETIC and genetic studies of the alkaline phosphatases in D. melanogaster have demonstrated that most of these enzymes are probably tissue specific, and are controlled by at least two separate genetic loci1,2. It was recently reported that a gene locus on chromosome III previously found to control electrophoretic mobility and enzyme activity of a larval skin phosphatase band also controls mobility and activity of the pupal phosphatase band, and it was suggested that these two phosphatases share a common molecular unit, controlled by a single gene locus3. The experiments reported here suggest that pupal phosphatase band is modified larval skin phosphatase which has been altered by exposure to larval gut enzymes in early pupation.

Methods for homogenization of flies, starch gel electrophoresis and staining for phosphatase have been described before2. It was initially decided to purify the phosphatases, and as a first step, extractions of fly homogenates with n-butanol were carried out using standard procedures. When butanol extracts of homogenates of 3 day old larvae were subjected to electrophoresis, however, it was found that the larval skin phosphatase band was transformed into a more electronegative band migrating at the same rate as the pupal band. Butanol treatment did not affect the mobility of larval gut bands or the pupal band, and if butanol extracts were made from dissected larval skins, rather than whole larvae, there was no change in mobility. Butanol seems to transform larval skin bands to pupa-like bands indirectly, probably by extracting some transforming substance from larval gut. When larval guts were dissected and homogenized separately, and then combined with a larval skin homogenate, the transformation of larval skin band to pupa like bands occurred in the absence of butanolization (Fig. 1), and butanol extracts of these mixtures produced no further changes. Boiling the larval gut homogenate destroyed the transforming factor. This factor does not seem to be a phosphatase. Larvae homogenized in 0.25 molar sucrose were centrifuged at 105,000g for 1 h. The skin transforming factor was found in the supernatant alone, but all phosphatase bands were present in both the supernatant and precipitate.

Because it seemed likely that the skin transforming factor is a larval gut enzyme, larval skin homogenates and gut homogenates were separately incubated with individual purified enzymes from various sources. zymes were added in concentrations of 0.75 mg/ml. in buffers of appropriate pH at 25° C and at 37° C. Samples of treated and control homogenates were examined electrophoretically. The results are shown in Table 1.

Table 1. TRANSFORMING ACTIVITY OF VARIOUS ENZYMES

Scoring was based on the rapidity and completeness of transformation.

Bovine trypsin was the most active enzyme in transforming larval skin phosphatase bands to bands with mobility identical to pupal bands (Fig. 1). The transformation was complete after 30 min of incubation at either 25° C or 37° C. Treatment of larval gut homogenates with trypsin resulted in the loss of midgut bands, and the same treatment of whole adult homogenates similarly

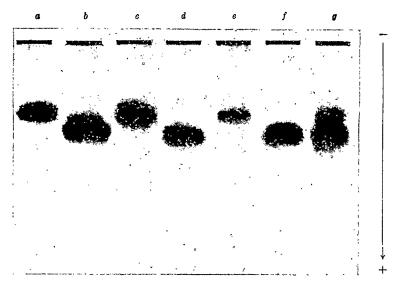

Fig. 1. a, Larval skin; b, larval skin and trypsin; c, larval skin and trypsin inhibitor; d, larval skin and larval gut: e, larval skin and larval gut and trypsin inhibitor; f, larval skin and papain; g, larva and pupa.

resulted in the loss of midgut bands, but there was no effect on the mobility or activity of other bands. Although porcine lipase had transforming activity, the preparation used was found to contain about 4 γ of trypsin/mg of protein. The addition of soybean trypsin inhibitor abolished the transforming activity of this lipase, trypsin, α-chymotrypsin, and also of larval gut homogenate (Fig. 1), which suggests that the skin transforming factor in the larval gut is trypsin or a trypsin-like enzyme. The activity of papain even in the presence of trypsin inhibitor suggests that transforming activity may be possible by means of differing mechanisms.

To compare further the properties of these phosphatase bands, untreated larval homogenates, butanolized larval homogenates, and untreated pupal and adult homogenates were each incubated for I h at 60° C. Samples were withdrawn at 10 min intervals and submitted to electrophoresis. Larval skin bands, transformed skin bands and pupal bands were resistant to this treatment, but all other bands were absent after 10 min of heating. In addition, when these homogenates were treated with ammonium sulphate solutions of varying concentrations, it was found that larval skin bands, transformed bands and pupal bands all precipitated in the 35-60 per cent range, while other phosphatase bands precipitated at different ranges of ammonium sulphate concentration.

The pupal phosphatase band activity comes solely from the yellow body, a structure that is said to be derived from sloughed larval gut⁵. In normal development, the gut bands seen in young larvae disappear in older third instars. The skin band, which has strong activity in third instar larvae, disappears in prepupae. The pupal band appears as the skin band is lost, and persists to the first few hours of adult life. These findings may be explained as follows: gut phosphatase is destroyed during the histolysis of gut occurring in mature larvae. Larval skin phosphatase, perhaps accompanying skin cells, is trapped in the yellow body during histolysis, is then exposed to the activity of trypsin-like enzymes released from gut cells, and is modified but not destroyed. This modified band is lost when the yellow body is passed out of the adult gut. The nature of the modification of larval skin phosphatase is unknown. Neuraminidase, however, is known to affect the electrophoretic mobility of alkaline phosphatase and other enzymes⁶, presumably by splitting off sialic acid residues, and perhaps a comparable reaction occurs with trypsin.

The relationship of alkaline phosphatases from different tissues in Drosophila and most other organisms is still

These experiments emphasize the dangers obscure. encountered in the interpretation of isozyme patterns, even when electrophoretic analysis is accompanied by genetic studies.

Glial \alpha-Glycerophosphate Dehydrogenase and Central Myelination

A PREVIOUS study of oxidative enzyme activity in the macroglia of adult cat optic nerve¹ has shown that α-glycerophosphate dehydrogenase (GPDH) activity which is not linked to NAD is localized exclusively in astrocytes. This suggests active involvement of these cells in lipid metabolism. Astrocytes are distributed in association with myelinated nerve fibres in the postlaminar part of the optic nerve, with myelinated and non-myelinated fibres in the lamina cribrosa and with nonmyelinated fibres in the prelaminar part of the nerve. Astrocytes alone of the macroglia cells are associated with the myelinated fibres within the lamina cribrosa³. For these reasons it has been suggested that astrocytes may support the myelin sheath of the adult central nervous system.

In this investigation, the techniques previously applied to the demonstration of GPDH activity in cat optic nerve1 were used to demonstrate enzyme activity in kitten optic nerve at six developmental stages: 6-7, 10-12, 15-16, 23, 28-29 and 38 days after birth. Myelination was studied at the same time using both cryostat sectioned material and optic nerves fixed in calcium formol and sectioned on a freezing microtome. The stains were sudan black, Luxol fast blue and osmium tetroxide.

Myelin sheaths stainable with sudan black and Luxol fast blue extended to within 4 mm of the lamina cribrosa 6-7 days after birth: in the third week they had reached to within 2 mm of the lamina, and at 23 days and thereafter as far as the posterior border of the lamina. There was thus evidence of centrifugal advance of myelination. Osmiophilia, however, was absent from the nerve fibre bundles during the first four developmental stages examined. In optic nerves from 28-29 day old kittens, the bundles of fibres were intensely osmiophilic to a level approximately 0.5 mm behind the lamina cribrosa: at 38 days and in the adult cat osmiophilia extended to the posterior border of the lamina. Osmium tetroxide seems to be a reliable indicator of unsaturated bonds in the fatty acids of myelin3, and so it is suggested that the relatively late appearance of osmiophilia indicates a difference in the unsaturated fatty acid content of "early" and "late" myelin.

In material from kittens of the first three age groups studied, stellate glioblasts present throughout the optic nerve showed intense GPDH activity. At 23 days and 28–29 days substantial GPDH activity was found in the glial cell columns within the prelaminar part of the optic nerve and the lamina cribrosa, and in glioblasts in the post-laminar part of the optic nerve within about 0.5 mm of the posterior border of the lamina. More posteriorly GPDH activity was virtually absent, only an occasional stellate cell showing very weak staining. In contrast, at the 38 day stage, post-laminar astrocytes throughout the optic nerve exhibited intense GPDH activity and, as before, this was also present in the glial cell columns at the head of the optic nerve. The situation characteristic of the adult cat optic nerve was thus established.

There seem to be three alternative explanations for the presence of an intense GPDH activity in glioblasts and astrocytes: first, that the breakdown of lipids provides a source of energy5; second, that the a-glycerophosphate cycle operates with the rapid production of energy and the oxidation of reduced NAD; third, that carbohydrates are being used in the biosynthesis of phosphatidic acids and thus phospholipids. To be effective in the rapid production of energy, however, the GPDH system probably needs to operate in conjunction with the citric acid cycle as a complex multienzyme system⁶ and such a system is unlikely to operate in the neonatal optic nerve of cat in which activity of enzymes of the citric acid is virtually undemonstrable in the first 2 weeks?. The idea of the GPDH in glioblasts and astrocytes being concerned in the biosynthesis of phospholipids is attractive because these cells also show an intense reaction for the presence of enzymes of the phosphogluconate oxidative pathway⁴ which is one of the principal sources of reduced NADP, utilized in the biosynthesis of fatty acids.

Furthermore, such considerations accord well with the histological context of glioblasts and their association with advancing myelination as demonstrated by sudan black and Luxol fast blue staining: for they are the only cells present in the neonatal kitten, and so at least some of them must be concerned with the local deposition of myelin and thus with phospholipid synthesis. In the adult cat, laminar astrocytes are the only macroglial cells present in a region of finely myelinated nerve fibres2: presumably these are the sheath supporting cells of the region and are concerned with some slow phospholipid turnover. It seems reasonable to assume a similar sheath supporting role for post-laminar astrocytes which are similar in morphology² and histochemical profile¹. Within the model, however, are the prelaminar glioblasts and astrocytes which have similar histochemical profiles1 but are isolating and insulating axons which remain unmyelinated: it may be that isolation and insulation require synthetic activity of a similar kind

whether or not these processes entail the formation and support of a myelin sheath.

The absence of GPDH activity from glioblasts further than 0.5 mm behind the lamina cribrosa in the fourth and fifth week is intriguing: it suggests that the maturation of myelin from the "early" non-osmiophilic type to the "late" osmiophilic type is not dependent on active lipid metabolism. At this stage, however, there are present oligodendroblasts which are developing their complement of citric acid cycle enzymes?: perhaps these cells provide the energy for the maturational change.

Oxidation of NADPH by Polymorphonuclear Leucocytes during Phagocytosis

It is now known that the phagocytic process in polymorphonuclear leucocytes (PMN) is accompanied by marked increases in the rates of oxygen consumption, glucose oxidation by the hexosemonophosphate shunt (HMPS) and oxidation of formate to carbon dioxide1-3. The energy for the phagocytic process seems to come from glycolysis1. The rate of glucose oxidation by the shunt in leucocytes seems to be regulated by the intracellular concentration of NADP (refs. 3 and 4). A suitable hypothesis for the enzyme basis underlying the metabolic stimulation in PMN during phagocytosis should therefore include a mechanism for the reoxidation of NADPH. Attempts have been made to correlate the stimulated activity of the hexosemonophosphate shunt in phagocytosing leucocytes with increased oxidation of NADPH. The evidence indicates that oxidation of NADPH in phagocytosing leucocytes is not accomplished by the classical route of hydrogen transport by way of cytochrome reductase and cytochrome c (ref. 1). Evans and Karnovsky⁵ have presented evidence for the existence in PMN cell extracts of an NADP-linked lactate dehydrogenase which is activated at low pH. Results obtained by Iyer, Islam and Quastel² indicated that PMN possess an enzyme system capable of oxidizing NADPH and NADH by a reaction involving the formation of hydrogen peroxide. The enzyme, however, was found to be much more active towards NADPH than NADH and its activity was strongly enhanced by manganese ions. Later Roberts and Quastel⁶ reported that the NADPH oxidase in PMN was probably peroxidase. Based on the available evidence, a mechanism was proposed to account for the metabolic changes observed in PMN during phagocytosis. This is seen as follows.

Results described here suggest that the NADPH derived from accelerated HMPS activity in phagocytosing PMN is not oxidized by lactate dehydrogenase. This and other recent findings have implications in relation to the mechanism of NADPH oxidation in PMN.

Polymorphonuclear leucocytes were prepared by injecting guinea-pigs intraperitoneally with 20 ml. of 12 per cent sodium caseinate and collecting the peritoneal exudates after 16-18 h¹. Microscopic examination of this preparation showed the following differential count: 84 per cent neutrophils; 9 per cent monocytes; 6 per cent eosinophils; 1 per cent lymphocytes. The leucocytes were washed twice with 10-15 volumes of cold calcium-free Krebs-Ringer phosphate solution.

Phagocytosis experiments were carried out in 125 ml. Erlenmeyer flasks immersed in a temperature controlled water bath shaker at 37° C. Each flask usually contained 15 ml. of Krebs-Ringer phosphate solution free of calcium, 5 mmolar glucose, 500 mg (wet weight) of cells, and 50 mg of polystyrene latex spherules (1.3µ in diameter) where indicated. The incubation was carried out for 30 min. At the end of the experiment the cells and particles were removed by centrifugation and the resultant supernatant was used for the estimation of lactic acid and hydrogen peroxide. Lactate was isolated from the incubation medium by first removing the residual glucose by the copper-lime method, and then extracting the acidified aqueous phase for 24 h with diethyl ether. The ether extract was evaporated to dryness and the residue was dissolved in a small volume of water. The extracted lactic acid was further purified by ascending paper chromatography. The solvent system used was tert-butanol (10): formic acid (2): H_2O (15). After developing and drying the chromatograms, lactate was eluted from the paper and used for specific activity determinations. Lactic acid was assayed by the method of Barker and Summerson⁸. Radioactivity was measured in a Packard liquid scintillation counter with the solvent of Davidson and Feigelson⁹. Assays for hydrogen peroxide were carried out on incubation media by the periodate method10.

3-3H-glucose has been shown to be the substrate of choice for investigating the function of NADPH in reductive reactions¹¹. According to established schemes of glucose metabolism in the animal cell, tritium from the 3 position of glucose will be transferred to NADP in the 6-phosphogluconic dehydrogenase reaction yielding NADP³H. Because PMN have been shown to be devoid of transhydrogenase activity, NADH should not be labelled with tritium from the 3 position of glucose. It can also be seen that the tritium from the 6 position of glucose will not be transferred to either NADP or NAD, but that lactic acid derived from 6-3H-glucose will

be labelled with tritium at the β -position. Results summarized in Table 1 indicate that in the presence of 6-3H-glucose the specific activity of lactic acid synthesized by phagocytosing PMN is almost the same as that derived from resting cells. Experiment also showed that the magnitude of the incorporation of tritium label from the 3 position of glucose into lactate was almost 32 per cent higher in resting leucocytes than in phagocytosing PMN. If, according to the scheme proposed by Evans and Karnovsky, the oxidation of NADPH in phagocytosing PMN was accomplished by an NADPlinked lactate dehydrogenase, there should have been considerably more tritium incorporated from the 3 position

of glucose into lactic acid in phagocytosing PMN than in resting cells. This apparently is not the case. We were not able to determine the extent of incorporation of tritium into hydrogen peroxide because of the rapid equilibration of 3H2O2 with H2O. Results presented in Table 2, however, indicate that the rate of peroxide formation by phagocytosing PMN is nearly double that of resting leucocytes. The observation that the rate of oxidation of formate to carbon dioxide in phagocytosing PMN is also about twice that of resting leucocytes 12 suggests that the latter process which is catalysed by leucocyte catalase is dependent on the availability of hydrogen peroxide. Paul et al.13, using a fluorometric assay for hydrogen peroxide, have observed a two to four-fold increase in peroxide formation in PMN after particle ingestion. These investigators have also noted a correlation between production of hydrogen peroxide in PMN and intracellular killing of bacteria¹⁴.

The finding that incubation of phagocytosing PMN with 1 mmolar sodium azide results in a significant elevation of tritium incorporation into lactic acid from the 3 position of glucose may imply that when NADPH oxidation by peroxidase is inhibited more of the reduced nucleotide is oxidized by lactate dehydrogenase. This, then, would assure an adequate supply of NADP for operation of the hexose monophosphate shunt during phagocytosis. It may be that in resting leucocytes the production of NADP through action of peroxidase is adequate even when the enzyme is inhibited with azide and thus increased oxidation by lactate dehydrogenase is not observed.

Relationship between Vitamin E and Certain Enzymes dependent on the Sulphydryl Group

VITAMIN E was discovered in the 1920s and its physiological role has still to be demonstrated1. Much of the interest in this vitamin has centered around its casual relationship in the events leading to a vitamin E deficient myopathy in several animal species²⁻⁴.

Ames and Risley⁵ suggested that essential sulphydryl groups of enzymes may be sites which are protected by the antioxidant action of vitamin E. This report examines enzymes which are unique and important to muscle and which depend on intact sulphydryl groups for their activities: myofibrillar ATPase, which provides energy for contraction⁶; and supernatant ATPase, which is the source of energy necessary for the accumulation of calcium ions by the sarcoplasmic reticulum during relaxation?.

English strain guinea-pigs were maintained on vitamin E sufficient and deficient diets as described before. Heart, masseter and gastrocnemius muscles were examined after 15 and 21 days.

The tissues were prepared by the procedure of Perry and Grey⁸. Myofibrillar and supernatant ATPase activities were determined by the method of Baird and Perry¹⁰ and expressed as activity/mg of non-collagen nitrogen (NCN)11. Sulphydryl groups were quantitated by a modification of the Ellman method12 and expressed as moles of sulphydryl groups/mg of non-collagen protein¹³. The sulphydryl inhibitor N-ethylmaleimide (NEM) was tested on heart supernatant fractions at a concentration of approximately 1 mole of NEM/mole of —SH in the supernatant.

All preparative procedures and assays were completed on the day animals were killed. Results of the ATPase and sulphydryl assays were analysed statistically by the F test. The effect of NEM on sulphydryl groups was analysed by Student's t test on paired observations. A probability of ≤0.05 was accepted as revealing a significant difference.

No significant differences were found in any category after 15 days. After 21 days, the E+ (vitamin E sufficient) gastrocnemius myofibrillar ATPase activity was significantly greater than the E- (vitamin E deficient) activity (Table 1). This was the only significant difference in the fibrillar fraction of the tissues examined. Heart and gastrocnemius supernatant ATPase of E+ animals was significantly greater than the corresponding fractions from E- animals.

Assay of tissue-free sulphydryl groups revealed no significant differences between the dietary groups. The average free sulphydryl group content of eleven E+ and E- supernatant fractions from each muscle was (moles ×108/mg of NCP): heart, 6.9; masseter, 5.8; gastrocnemius. 6.6. The average free sulphydryl group content of ten E+ and E- myofibrillar samples from each muscle was: heart, 5.1; masseter, 5.3; and gastrocnemius, 5.3. The inhibitory effect of NEM on E - heart supernatant sulphydryl groups was, however, significantly greater than its effect on the corresponding E+ fraction.

A point to emphasize is the investigation of animals in the initial stages of vitamin E deficient myopathy. The appearance of effects caused by decreased vitamin E in the heart and gastrocnemius muscles, but not in the masseters, suggests that these changes are related to the onset of the myopathy. The gastrocnemius muscle is a primary target of nutritional muscular dystrophy, while it is not yet clear to what extent the heart is affected. The masseter seems to have little if any involvement in short-term studies of the vitamin E deficiency syndrome of guinea-pigs10.

Localization of the effects of vitamin E deficiency in the sarcoplasmic reticulum would provide a possible explanation for some symptoms of the myopathy. A defect in the functional integrity of the reticulum, such

as could be caused by the labilization of sulphydryl groups essential for ATPase activity, would initially affect the calcium binding ability of the system, and have a secondary effect on the membrane structure. It seems that in mice with hereditary dystrophy, the ability of the membrane to release calcium can be enhanced by nitrate ions to a greater extent than in the normal controls14, suggesting that the properties of the calcium binding sites in the membrane have been altered by this dystrophy. Guineapigs fed a vitamin E deficient diet have a significant increase in serum creatine phosphokinase activity after 21 days15. This enzyme is of muscular origin16, and the permeability of the muscle cell membrane to this enzyme seems to have been altered.

The negative results of the sulphydryl assay on the muscle tissues studied imply that vitamin E has no direct or general effect in maintaining sulphydryl groups in the reduced state. Conversely, the effect of vitamin E deficiency on several enzyme systems dependent on sulphydryl, and the increased susceptibility to NEM of heart supernatant sulphydryl groups from vitamin E deficient animals, implies some indirect relation between tocopherol and sulphydryl groups. Possibly in the living system the active form of the vitamin can mask some sulphydryl groups by the reversible formation of a mercaptole or hemimercaptole¹⁷, or by substitution by the sulphydryl group at the 8a position of α-tocopherol, as reported by Goodhue and Risley¹⁸. Substituted α-tocopherones have not been isolated from biological materials. This may, however, be because they are easily reduced to α -tocopherol or hydrolysed to α -tocopherolquinone¹⁸.

Possible Sources of the Carbonate Fraction of Egg Shell Calcium Carbonate

THE classical theory of the mechanism of production of the carbonate fraction of the calcium carbonate of the hen's egg shell is that of Gutowska and Mitchell¹. This theory makes use of the enzyme carbonic anhydrase which occurs in the glandular cells of the shell gland in large amounts. It can be represented thus

Blood Shell gland Lumen
$$2HCO_3^- \rightarrow 2HCO_3^- \rightarrow H_2CO_3 + CO_3^- \rightarrow CO_3^- \rightarrow Egg shell$$
 $\uparrow \downarrow \text{ carbonic anhydrasc}$
 $H_2O + CO_9$

There is little evidence in favour of this theory; in fact, the very low solubility product of calcium carbonate makes it unlikely that calcium and carbonate ions could be secreted together by the tubular glands of the shell gland. This would result in crystallization of calcium carbonate within the glands². Because of this lack of evidence the following experiment was designed to provide evidence

either for or against the theory.

White Leghorns in a stage of active shell formation (ten birds) or without an egg in the shell gland (controls: ten birds) were anaesthetized and the sciatic artery and vein and the inferior oviducal vein were cannulated³. Injections were made into a wing vein of either: 0·1 mc. of ¹⁴C-sodium bicarbonate (specific activity 57 mc. of carbon-14/g of sodium bicarbonate), or 0·2 mc. of ⁴⁵Ca-calcium chloride (specific activity 0·196 mc. of calcium-45/mg of calcium chloride) in 2·5 ml. of 0·9 per cent saline. Samples of blood were taken from the cannulae at 15 (⁴⁵Ca) or 30 (¹⁴C) min intervals. Activities of deproteinized (methanol) plasma were determined in a liquid scintillation spectrometer. The arterio-shell gland venous (AV) differences of both ⁴⁵Ca and ¹⁴C are given in Table 1.

Table 1. ARTERIO-SHELL GLAND VENOUS DIFFERENCES OF CALCIUM-45 OR CARBON-14 ACTIVITY OF PLASMA WITH RESPECT TO THE FUNCTIONAL STATE OF THE SHELL GLAND, AFTER INJECTION OF LABRLLED CALCIUM CHLORIDE OR SODIUM BICARBONATE

Activity/ml. of deproteinized plasma from sciatic artery (100) minus activity/ml, of deproteinized plasma from the uterine vein

Injections were of 0.2 mc, of $^{46}\text{Ca-calcium}$ chloride or 0.1 mc, of $^{14}\text{C-sodium}$ bicarbonate.

* t Test.

When the logarithm of the activity/ml. of plasma was plotted against time, the pattern of removal of calcium-45 during egg shell formation was considerably different from that in non-calcifying hens. On the other hand, the pattern of removal of carbon-14 from the blood was almost identical in both experimental and control birds.

Analysis of the egg shells from the experimental birds showed that although 45–50 per cent of the calcium-45 dose was deposited in the shell within 150 to 180 min, only 3–5 per cent of the carbon-14 was deposited within 180 to 220 min. When equivalent doses of ⁴⁷Ca-calcium chloride and ¹⁴C-sodium bicarbonate were injected simultaneously into the wing veins of five unanaesthetized birds, amounts similar to the former ones were recovered from the shells after periods of 120 min (38–45 per cent of the dose of calcium-47 and 1–3 per cent of the dose of carbon-14).

If Gutowska and Mitchell's theory is correct, when producing the carbonate fraction of the shell the gland must remove amounts of bicarbonate from the blood which are at least equivalent to the amounts of calcium which it

removes. From a simple calculation based on the quantities of both calcium and bicarbonate present in the blood, it is evident that an AV calcium-45 difference of about 60 per cent would imply an AV difference of at least 8 per cent in the content of labelled sodium bicarbonate if Gutowska and Mitchell are correct. Table 1 shows that there is no AV difference of carbon-14 during shell formation or during shell gland quiescence and the patterns of removal of carbon-14 from the blood indicate that the shell gland takes little or no part in this process.

Although no AV difference in the carbon-14 content of the plasma was detected during shell formation, up to 5 per cent of the dose was found in the shells. It is presumed that the carbon-14 activities in the shells were caused by ¹⁴C-carbon dioxide which originated from the ¹⁴C-sodium bicarbonate. This suggestion is supported by the fact that similar activities were determined in the egg shells of hens dosed with glucose labelled with carbon-14.

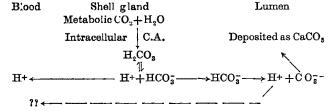

These results, together with the objections put forward by Diamantstein and Schlüns², suggest that Gutowska and Mitchell's theory is no longer tenable. If this is so, what alternative theories can be put forward? One possibility can be represented thus

Blood Shell gland Lumen
$$HCO_3^- \rightarrow Shell gland$$
 tubular glands $\rightarrow HCO_3^- \rightarrow H^+ + CO_3^-$

/ Deposited as CaCO₃

This suggestion, however, still relies on the removal of bicarbonate from the blood by the shell gland, although the calculated AV difference in ¹⁴C-sodium bicarbonate would only be 4 per cent. Moreover, it does not account for the carbonic anhydrase in the shell gland cells.

Another theory has been proposed by Diamantstein⁴, in which the shell gland derives the shell carbonate from its own metabolic carbon dioxide production, thus

This mechanism would account for the presence of the carbonic anhydrase in the glandular cells, for the drop in the shell gland venous pH which occurs during shell formation^{3,5} and possibly also for the fluctuations in the blood bicarbonate which occur during shell formation⁶. Neither of these alternative theories, however, explains how the bicarbonate ions in the lumen of the shell gland are deposited as calcium carbonate. When carbonate ion is formed from bicarbonate ion a proton will be produced, but nothing is yet known of how this transformation occurs and what is the fate of the proton. In these theories the proton is tentatively shown passing into the blood. Any transformation of bicarbonate to carbonate would have to take place in close proximity to the actual site of shell formation, for the carbonate would tend to crystallize out as calcium carbonate in situ. A possible explanation of carbonate formation put forward by Robinson and King? has been denied by Diamantstein, Bronsch and Schlünse.

The experimental results described here give considerable support to Diamantstein's hypothesis, although they do not provide proof of it.

Stoichiometry and Coupling: Theories of Oxidative Phosphorylation

An integral and constant stoichiometric ratio is usually assumed to relate to coupled metabolic processes. In particular, the ratio of ATP production to oxygen consumption (P/O) is considered integral and constant in all discussions of oxidative phosphorylation. This view is maintained despite the fact that it conflicts with a great deal of experimental evidence¹. Although the discrepancies are often explained on the basis of technical difficulties, Slater² has pointed out that some uncoupling may represent physiological reactions, and that it is probably not possible completely to eliminate "uncoupled" reactions. We feel that despite the recognition of intrinsic uncoupling, its true significance has not been appreciated. Mechanisms and efficiency are still invariably assessed in terms of stoichiometry. We shall discuss some sources of non-stoichiometry, and then consider the implications of incomplete coupling, with particular reference to theories of oxidative phosphorylation.

Sources of non-stoichiometry or uncoupling can be divided into two categories: scalar sources and vectorial sources (processes respectively independent of and dependent on the symmetry of the system). Considering the scalar sources, a general scheme involving two coupled reactions is shown in Fig. 1. Here the oxidation of A and reduction of B are coupled to the phosphorylation of ADP. Oxidative phosphorylation is usually described in terms of such a scheme, with the belief that there is a stoichiometric relation between the oxidation and phosphorylation reactions. It is clear, however, that this need not necessarily be the case. For example, Fig. 2 shows the detailed scheme of reactions involved in a well known case of substrate level phosphorylation, the oxidation of acetaldehyde by NAD+ in micro-organisms3. In this system, deviations from stoichiometry can result from side reactions involving any of the reactants or products in

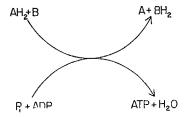

Fig. 1. General scheme for coupling of oxidation to phosphorylation.

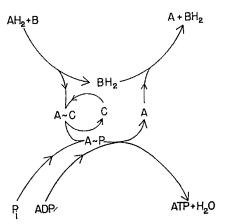

Fig. 2. Substrate level phosphorylation involving the oxidation of acetaldehyde by NAD+ (C is coenzyme A).

the two principal chains. These are trivial side reactions, easily recognized by lack of stoichiometry in the oxidation and phosphorylation reactions considered separately, and easily corrected for. The more interesting sources of decoupling arise from hydrolysis and other side reactions of the intermediate which links the two reactions, that is, $A \sim C$. Although the stoichiometry of the chief reactions is undisturbed, there is a deviation from the "theoretical ratio" relating them to one another.

In the example shown in Fig. 2, the coupling, although not perfect, is fairly tight as would be anticipated from the stability of the intermediates. But the situation may be very different in the case of respiratory chain oxidative phosphorylation. The "chemical" theories invoke mechanisms similar to that described in Fig. 2. The inability, however, to identify the intermediates (which may simply be molecules in an excited state) is usually explained by their supposed lack of stability. If the rates of breakdown of high energy intermediates are comparable with the rate of oxidative phosphorylation, there will be significant uncoupling.

In the foregoing scheme the coupling is effected by the transfer of bonds or groups at each step. Coupling may also occur by means of electron transfer. More generally it is the transfer of energy which is important, whether or not any chemical group is transferred. Intermolecular energy conversion between different excited molecules, involving changes in their electronic states only, is not uncommon4.

Considering the vectorial sources of non-stoichiometry or uncoupling, many reactions which are encountered in bioenergetics take place in a structural environment, an important example being oxidative phosphorylation in mitochondria. In such systems, compartmentalization of the reactants and products, and orientation of the enzymes, introduce the possibility that vectorial forces (for example, concentration gradients, potential gradients) may influence the coupling between reactions. In oxidative phosphorylation this can occur in at least two ways. First, if the reactions are coupled to each other through a high energy intermediate as in Fig. 2, and if they are both coupled to a transport process through the same intermediate, the electrochemical potential gradient of the transported species will influence the rates of oxidation and phosphorylation, and the P/O ratio. Second, the coupling may not be effected through a high energy intermediate, but directly by a transport process, for example, of a proton as suggested by the "chemiosmotic" hypothesis. In both cases, the extent of leakage (or exchange) of the transported species will influence the ratio of reaction rates. (In the case of an active transport mechanism involving a "pump", for example for protons, uncoupling may occur as a consequence of either scalar or vectorial processes. No specific molecular mechanisms are known, and so it is unnecessary to speculate on the origin of uncoupling; unpublished work of Essig, Caplan and Kedem.

We see from the considerations given here that the general way of describing oxidative phosphorylation⁶

$$SH_2 + \frac{1}{2}O_2 + nADP + nP_1 \rightarrow S + nATP + (n+1)H_2O$$

may be misleading, in that n need be neither integral nor constant in different conditions. Specifically, n will vary if the rate of oxidation varies although physical characteristics of the system such as the permeability of any leakage pathway and the concentrations of enzymes and cofactors remain constant. (In terms of the linear phenomenological equations of non-equilibrium thermodynamics, n will vary with changes in the forces and the flows even though the phenomenological coefficients and hence the "degree of coupling" may remain constant7.)

These considerations are important in the current controversy between two important theories of oxidative phosphorylation, the chemical and the chemiosmotic hypotheses. Arguments for and against each of these are usually based on stoichiometric considerations^{8,9}. example, the experimental P/O ratio discussed previously, and the ratios H^+/O , Ca^{2+}/H^+ and $\sim P/K^+$ are all supposed to reflect integral numbers, despite the fact that oxidation rates, pH, osmolality and ion concentrations all greatly affect the observed values^{1,10-13}. The emphasis placed on stoichiometry can be appreciated from the following recent quotations. Mitchell and Moyle's state that "The observed \rightarrow H⁺/O and \rightarrow H⁺/2e⁻ quotients. are in accord with the chemiosmotic conception of the folding of the respiratory chain into three proton-translocating o/r loops. The observations would be difficult to reconcile with the orthodox chemical coupling conception . . .". On the other hand, Slater14 states that "The stoichiometry of proton extrusion by mitochondria and of proton uptake by chloroplasts . . . (is) difficult to reconcile with the chemiosmotic hypothesis". although the proponents of each theory disagree in their interpretation of the data, they are agreed on the central importance of stoichiometry in deciding the issue. The foregoing considerations suggest, however, that constant stoichiometric ratios would not be expected in either case, and thus a choice cannot be made on this basis.

The assumption of complete coupling can lead to misinterpretation of experimental data in terms of the postulates of either model. For example, the number of

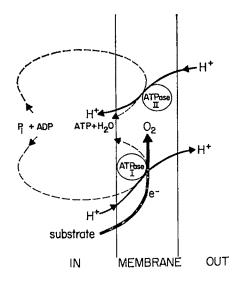

Fig. 3 A model for the coupling of oxidation, phosphorylation and proton translocation (see text).

proton translocating o/r loops in the chemiosmotic theory, or the corresponding number of phosphorylation sites in the chemical theory, may be underestimated.

Proponents of the two theories discuss ratios in terms of complete coupling and assume on this basis that their respective models are incompatible. This is not necessarily the case. A combination of the two is possible, as shown in Fig. 3. In this scheme, electron transport through the respiratory chain is coupled chemically to ATP synthesis by ATPase I, and also drives the translocation of H⁺. In addition, ATPase II couples the back flow of H+ to ATP synthesis. Either mechanism may be predominant.

An experimental evaluation of the various mechanisms would require measurement of the rates of hydrogen translocation, phosphorylation and oxygen uptake as functions of the forces. These are: the electrochemical potential difference of H+ across the membrane; the phosphate potential"; and the substrate/product ratio. The conventional presentation of data in the form of stoichiometric ratios without reference to the rates of reaction and the driving forces is inadequate.

PATHOLOGY

Interaction of some Polyvinylpyridine Oxides with Polysilicic Acid and its relationship to their Ability to inhibit Silica Fibrosis

FINELY divided silica produces fibrotic lesions when it is inhaled or injected into the lung. The mechanism by which silica exerts its pathogenic effects has not been established but it is probable either that it functions by absorbing some cell constituent onto surface silanol groups or that, after particles have been ingested by phagocytes. monosilicic acid which is produced when silica dissolves in the cytoplasm exerts the cytotoxic action. In either case silanol groups are involved.

Poly-2-vinylpyridine 1-oxide will inhibit the fibrogenic action which quartz usually exerts when it is injected into animals or inhaled and evidence of any interaction

between this polymer and silanol groups may be of interest in explaining its chemotherapeutic action. In a preliminary communication², it has been shown that monosilieic acid in concentrations below 0.01 molar produces a bathochromic shift in the ultraviolet absorption spectrum of poly-2-vinylpyridine 1-oxide. A similar shift is not observed when monosilicic acid is added to 2-ethylpyridine 1-oxide. A slight shift in the spectrum of poly-4-vinylpyridine-1-oxide in the presence of monosilicic acid indicates that there is also some interaction between the 4-isomer and monosilicic acid. These deductions have been confirmed by viscosity measurements. The interaction presumably involves hydrogen-bond formation between the N-oxide group and the silanol group.

Nash, Allison and Harington³ have shown that there is also interaction between poly-2-vinylpyridine 1-oxide and polysilicic acid because a precipitate is formed when solutions of the two are mixed, and this again indicates hydrogen bonding. The implied correlation between hydrogen bonding and chemotherapeutic activity has been examined by synthesizing a number of other pyridine oxide polymers, and the ability of these and of poly-Nvinylpyrrolidone to precipitate polysilicic acid has been observed. The ability of each to counteract the cytotoxic effects of silica was measured by adding each polymer to a culture of peritoneal macrophages to which silica powder had been added and comparing the survival times of the cells. (These tests were carried out by Dr Beck and Miss Sack in the Institut für Lufthygiene, Düsseldorf.) The results are summarized in Table 1. There is apparently no correlation between the ability of a polymer to inhibit the cytotoxic effect of quartz and its ability to precipitate polysilicic acid.

Table 1	
Precipitation with polysilicic acid†	Protective action against silica
· + +	Highly active Some activity
+	Inactive
+	Highly active
-	Inactive
-	Inactive
-	Active Inactive
	Precipitation with polysilicic acid† . + + + +

^{* 2} per cent w/v aqueous solutions. † 0.02 molar aqueous solution.

Further studies (unpublished) on the effect of monosilicic acid on the viscosity of solutions of poly-2-vinylpyridine 1-oxide and poly-4-vinylpyridine 1-oxide indicate that, while the complex formed by the first polymer is stable up to 60° C, that formed by the second is much less stable above 20° C. It seems that loose interchain crosslinks and links between proximate parts of a randomly coiled polymer chain are formed by monosilicic acid with poly-4-vinylpyridine oxide but that monosilicic acid is more intimately bound to poly-2-vinylpyridine oxide. Interaction between oxygen and alkyl group in 2-methyl pyridine oxide has been demonstrated. The type of bonding is probably present in poly-2-vinylpyridine 1-oxide because this polymer has a lower pK_a value than the 4-isomer. A model shows that the polymer structure would then be very compact with the oxygen atoms aligned so that monosilicic acid could become attached to the polymer by two or possibly three hydroxyl groups. Cross-linking would be less likely with poly-2-vinylpyridine oxide than with poly-4-vinylpyridine oxide.

It seems probable that the ability of poly-2-vinyl-pyridine oxide to exert a protective action against silica depends not merely on its ability to form a hydrogen bonded complex, for most N-oxides will form such complexes, but on the stability of the complex which is formed.

Carcinogens in Chinese Incense Smoke

CONSIDERATION of the high incidence of naso-pharyngeal cancer among the Chinese¹ led us to search for carcinogenic constituents in condensates from burning Chinese incense. Using thin-layer and column chromatography, several polycyclic aromatic hydrocarbons, including 3,4-benzopyrene, have been detected by ultraviolet absorption spectra. The 3,4-benzopyrene content was estimated fluorimetrically to be of the order 0.4 µg/stick of incense. The free radical content of the tar condensates was estimated by Dr A. Horsfield of Varian Associates Ltd. to be approximately 1.3×10^{15} stable electrons/g (comparable with the figure $1 \times 10^{16}/g$ obtained for cigarette tar³).

A search for nitrosamines in the condensate by the polarographic method4 gave negative results, but the method of Preussmann et al.5, and the Griess reagent, gave a salmon pink spot, R_F 0.35, on thin-layer chromatography (hexane: ether: dichloromethane, 4:3:2).

The same colour was, however, obtained by spraying the plate with sulphanilic acid (1 per cent in 30 per cent acetic acid) without the need of previous irradiation and of the second component of the Griess reagent, 1-naphthyl-

Nitrosamines do not give a colour with the sulphanilic acid reagent, but aromatic aldehydes give chiefly yellow colours. Furfuraldehyde which gives a slowly developing red colour similar to that of the unknown constituent of incense condensate has, however, a different R_F on thinlayer chromatography.

The colours given by aromatic aldehydes with sulphanilic acid should be borne in mind when applying the Griess reagent for the detection of nitrosamines according to the procedure of Preussmann et al.5.

We thank Professor K. Shanmugaratnam for the Chinese incense.

CYTOLOGY

Establishment of a Line of Cells from the Silkworm Bombyx mori

Following the establishment of lines of cells from tissues of the moth *Antheraea eucalypti* Scott¹ and the mosquito *Aedes aegypti* L.², a line of cells from the silkworm *Bombyx mori* L. has now been established.

The method of culturing the cells and the medium were the same as for the A. eucalypti cells. All the cultures were incubated at 29°-30° C. The cultures were set up in 1964 and consisted either of six whole ovaries torn apart or of dissociated cells from six ovaries suspended in 3·0 ml. of medium in Petri dishes. The ovaries were obtained from larvae which had started to spin their cocoons. Of the six cultures of whole ovaries, five died after 6 months and one survived for 12 months after it had been set up.

In the cultures of dissociated cells, most cells became attached to the substrate within 12 h. During the next 4-5 days many cells died, but by the tenth day the cultures were extremely healthy and dividing cells were common. Some cells formed sheets, very like syncytia, which attached firmly to the substrate. Short lengths of undissociated ovariole showed muscle contractions at 12 days. The sheaths surrounding these pieces of ovariole formed long processes that contracted regularly (Fig. 1). At the end of 6 months only two of the cultures had survived. Three months later, cells in one of these cultures rapidly increased in number. Most cells did not attach

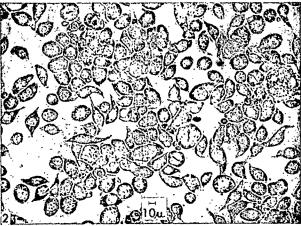

Fig. 1. Protoplasmic extensions which have formed a network, in a culture of silkworm ovarian cells. The network was contractile, 8 months in culture.

Fig. 2. Cells from the established line of silkworm cells 29 months in culture.

to the substrate. Two weeks later a subculture was made by transferring the cells to a new culture vessel along with half the medium. The remaining culture died 2 months later. The culture which had "transformed" and the subcultures continued to proliferate and further subcultures were made at 2–3 week intervals for 3 months. Since this time subcultures have been made at 6 day intervals.

The most common type of cell in the line is spindle-shaped, $12-25\mu$ wide and $50-70\mu$ long. The only other type of cell significant in number is slightly spindle-shaped to about $18-30\mu$ in diameter (Fig. 2). Many of these latter cells form small sheets on the surface of the culture vessel. The network of contracting tissue persisted after the "transformation". but by 16 months only single cells remained.

The generation time of the cells, measured 2 yr after the culture was set up, was 48 h. The cells have been adapted to grow in medium containing 1 per cent bovine plasma albumin and 1 per cent heat treated haemolymph from Antheraea pernyi (Guer.). The cells have been deep frozen in medium containing 10 per cent glycerol and have proved to be still viable after 10 months at -180° C.

Although the diploid number of chromosomes in the silkworm is 56, most cells examined 15 and 18 months after the line was established contained many more than 100 chromosomes.

Metaphase Arresting Compounds in Embryos

COLCHICINE, demecolcin (N-desacetyl-N-methylcolchicine) and vinblastine are all metaphase arresting agents¹. The first two compounds have been used extensively to determine various parameters of cellular dynamics, such as the mitotic index and the turnover time. In adults good agreement has been found between data obtained using colchicine and isotopes². Vinblastine is not used to examine these cell parameters, probably because it has been shown to affect DNA synthesis³. The effect of these compounds on embryonic rats in utero has been examined. In this study, we found that the mitotic index obtained using the different compounds differed profoundly.

Mitotic indices were obtained by counting one thousand cells in sections of the lining of the cerebral ventricles of twelve day embryo rats after administering the metaphase arresting agent intraperitoneally to the mother. The animals were killed 4 h after the administration of the drug. The number of mitotic figures found was expressed as cells in division per hundred cells over a period of 4 h. Nine embryos from three litters were examined at each dose level. In the absence of any metaphase arresting agent 7.4 per cent of the cells of the inner surface of cerebral ventricles were found in various stages in division.

Wegner et al.⁴ using ³H-thymidine reported that the generation time in different ectodermal and endodermal tissues in the rat embryo varied between 12 and 18 h. They also noted that the source of variation was in the G1 period, the S, G2 and M periods being fairly constant. The mitotic time was 1 h. We used this figure in this experiment and a generation time of 13.5 h is found. If the generation time is 13.5 h, then some 30 per cent of the cells should be found blocked in division after 4 h treatment with the arresting agent. The data pre-

sented in Table 1 are not only inconsistent with one dose and one drug but are at variance with the mitotic index determined from the generation time.

Table 1. REFECT OF METAPHASE ARRESTING AGENTS ON THE MITOTIC INDEX IN 12 DAY EMBRYO RATS

Drug	Mitotic ind 1 mg/kg	ex after 4 h 8 mg/kg
Colchicine Demecolcin	* 20 ±2†%	7·0±0·8% 6·6±0·7%
Vinblastine	6.8±0.4%	5.3 ± 0.8%

Metaphase arrest not seen in these embryos.
 † Standard deviation.

In the untreated embryos, 68-72 per cent of cells found in division were in metaphase and 15-17 per cent in anaphase. In the treated embryos 95-97 per cent of the cells found in division were in metaphase, but only 1-3 per cent were found in anaphase. This indicates that the cells were blocked in metaphase, and it can therefore be assumed that the unexpectedly low yield of mitotic figures was not caused by a lack of penetration of the drug through the placenta. Another cause for the small number of division stages might be the destruction of the arrested metaphase figures. This would not, however, be expected to occur during the relatively short duration of these experiments and no indication of such destruction was seen in the sections.

We examined the effect of demecolcin on embryonic mitotic indices and we came to the conclusion that the drug was causing some inhibition during interphase, and demecolcin has been reported to inhibit DNA synthesis in embryos in uteros. The same effect seems to be present with the other metaphase inhibitors, colchieine and

Whatever may be the cause of the differing mitotic indices produced by these different agents, the indices found in mammalian embryos in utero using these metaphase arresting agents do not correlate with the isotopic data of Wegner et al.4, nor do they reflect the mitotic activity of the untreated tissue.

APPLIED SCIENCE

Formation of Thin Polymer Films in a Glow Discharge

GLOW discharge polymerization of organic materials has already been described in detail. The process involves introducing vapours of relatively volatile monomers into a low pressure chamber (1 to 5 torr) and subjecting these to an A.C. discharge maintained between two parallel electrodes. Ions and electrons, produced in the glow, bombard the electrodes and the molecules in the gas phase; these interactions initiate complex chemical reactions which result in the formation of thin continuous coatings on the electrode surfaces. Film formation actually takes place by positive ion bombardment of monomer molecules adsorbed onto the electrodes. For a given monomer, the

composition of the films varies with the ratio of adsorbed molecules to the number of ions striking the surface and also with the degree of contamination produced by breakdown products formed in the gas phase.

This article is concerned with a modified glow discharge process—based on the mechanism referred to briefly here for depositing polymer coatings from non-volatile starting materials. Furthermore, the process is easily controlled and produces high quality coatings free of gas phase contaminants.

The apparatus used in this work is shown in Fig. 1a; steel samples about $60 \text{ cm} \times 7 \text{ cm} \times 0.025 \text{ cm}$ were shaped into a drum and placed in a 'Teflon' holder which could be rotated (Figs. 1b and 1c). Organic material (with V.P. ≤10-2 torr at 20° C) was evaporated from a heated boat onto the rotating drum at its lowest point. The deposited material was then subjected to ionic bombardment by initiating and maintaining a glow discharge between the rotating sample and a stationary electrode. This electrode was located above the highest point of the drum and about 1 to 4 cm away. The discharge was maintained in argon, precautions being taken to avoid contamination of the glow with organic material; for example, argon gas was injected into the system through the stationary electrode and diffusion of hot vapours away from the evaporation area was minimized by means of cold baffles.

Coatings up to 10 were built up on the rotating drum by successive evaporation and bombardment of layers 10-100 Å thick. Any attempt to deposit and bombard thicker layers resulted in films containing a large percentage of unreacted material, even when the number of ions striking the surface was in excess of that required to allow every deposited molecule to react. It was concluded that the maximum layer which could be processed was a function of the penetration of the ions formed in the discharge.

Coatings were readily produced from materials of widely differing structures, for example, butyl phthalate, acrylamide, uncured epoxy and polyester resins, silicones, liquid paraffin and linseed oil. Film properties were readily controlled—compared with conventional glow discharge polymerization—by varying the discharge In addition, the final current and evaporation rate. coatings were completely free of gas phase contaminants because the discharge was maintained in argon.

This technique could be attractive for depositing very thin coatings (<100 Å) on a moving substrate, but for coatings of 1μ and above it is clearly unsuitable because of the large number of deposition-bombardment cycles required. A possible method of depositing the thicker coatings would be to combine the two stages and run them concurrently—a technique similar in many respects to conventional glow discharge polymerization. This would however, re-introduce gas phase reactions which might result in excessive contamination.

A more feasible approach², with the exciting possibility of being developed into a high speed, solventless strip coating process, involves the use of more penetrating radiation. A high speed, low pressure (about 10-2 torr) technique has been developed by Williams and Moore for vapour depositing thin uniform films of a wide range of organic materials (for example, low vapour pressure monomers, uncured thermo-setting resins, natural resins, silicones, etc., and mixtures of such materials) without effecting any thermal degradation or fractionation during evaporation. It has been shown that these films can be either polymerized or cross-linked or both while still at reduced pressure by bombarding for a very short time with low energy electrons (<20 kV) at current densities up to 1 m.amp/cm². Attempts to produce coatings with similar properties to the present lacquers on tin-plate have been very promising. This method could be an extremely attractive lacquering technique; the vacuum required is moderate, the electron energies low and hence

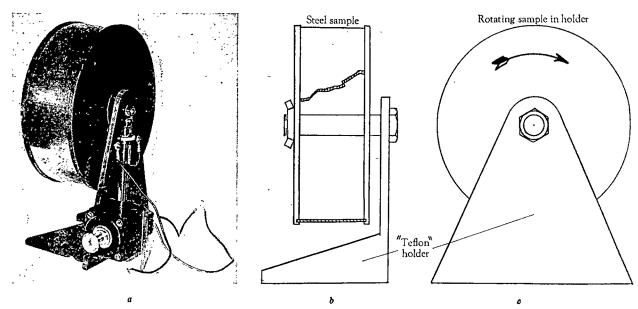

Fig. 1. a, b and c, Views of the apparatus used showing the rotating steel drum on which the polymer was formed and the 'Tefion' holder.

relatively inexpensive to produce, and because solvents and heating ovens are eliminated it has considerable advantages over the present process, especially for high speed applications.

GENERAL

Diesel Exhaust Particulates

Although the experimental techniques are available, limited effort has been made to characterize physically and chemically the particulate emissions from air pollution sources with respect to particle size, total surface area and chemical composition. If the potential to affect human health, property or atmospheric reactions or visibility of the particulate pollution, present in urban atmospheres, is to be evaluated, the nature of the contribution from each source will have to be more fully understood than at present. In this study, we focused on the characterization of particulates in a diesel engine exhaust.

Quantitative information available on diesel exhaust composition has, until recently, primarily pertained to gaseous constituents¹⁻⁵. Other studies were concerned with visible smoke and odour^{6,7}. Several investigations were made of the reactions and kinetics in the formation and combustion of smoke in hydrocarbon flames with controlled laboratory combustion chambers⁶⁻¹⁰. Others studied the relationship between smoke production, work parameters and fuel properties¹¹⁻¹³.

The engine used was a single cylinder, four cycle diesel. On acquisition the engine was completely overhauled and reconditioned; at the beginning of these tests it had accumulated approximately 500 h of prior running time. Although not of usual industrial size, the engine was not atypical in general design, speed, exhaust temperature, and carbon dioxide and oxygen emissions. Load was provided by driving a 5 kW generator, the output of which was dissipated through adjustable immersion

heaters. Engine specifications and fuel properties are shown in Table 1.

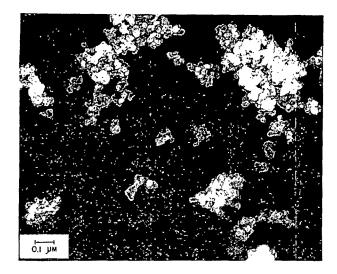

Table 1. ENGINE AND FUEL SPECIFICATIONS

* New York Central specification number 1,370-C, Grade 2.

All sampling for particulates was performed in the exhaust pipe approximately four inches from the exhaust valve. A vacuum pump was used to withdraw centreline samples at isokinetic flow. Air samples were metered with orifices, were not diluted, and were obtained at as high a temperature as possible in order to avoid moisture condensation. Engine speed was monitored with a stroboscope. Fuel consumption was determined from reservoir fuel volume changes during a test run. The fuel to air ratio was calculated after the carbon dioxide and oxygen content were determined by Orsat analysis.

Samples for electron microscopy were collected on carbon filmed glass slides in an oscillating thermal precipitator 14 . Electron photomicrographs were obtained after transferring the carbon films to the grids. Resulting micrographs were sized with a Zeiss TGZ 3 particle size analyser. From the number sized, photographic area and magnification, the number of particles per unit area of sample was calculated. The number concentration per unit volume of exhaust was obtained from the air sample volume and the area of particle deposit.

Samples for specific surface area and bulk density determinations were collected on 'Millipore GS' membrane filter. Specific surface area measurements were performed according to Brunauer, Emmett and Teller surface adsorp-

a

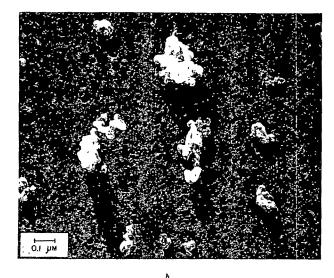

Fig. 1. Electron photomicrographs of diesel engine exhaust particulate (a) unshadowed and (b) shadowed with platinum, $(\times c.~58,000.)$ Sampled using a thermal precipitator 4 in. from the cylinder at engine operating conditions 1400 I.

tion theory¹⁵ and techniques¹⁶. Gravity-standing bulk density was determined by weighing the amount of material in a container of known volume. Weight concentrations of particulates (mg/m3) were determined by filtering through pre-weighed glass wool packed alundum thimbles and measuring the weight gain.

The free acidity of a sample of particulates, successively gathered and removed from a 'Millipore GS' filter, was measured (in the absence of carbon dioxide) by titrating with 0.01 normal sodium hydroxide in the presence of 85 per cent ethyl alcohol with mixed cresol red-thymol blue indicator. A twenty hour leaching period was used.

Table 2 summarizes our results. Operating conditions can be described as follows: 1400 I, idle speed, no load, low temperature; 1800 C, intermediate speed, no load, moderate temperature; 1800 L, reasonable load, resultant speed and temperature. The results show that the engine is a principal source of particles. Thus we found approximately 107 particles/cm3 released, while 103/cm3 is representative of the ambient air concentration of 0.1μ diameter particles17. A dilution factor of 104 would be required to reduce particle numbers to ambient concentrations.

Table 2. CHARACTERISTICS OF DIESEL EXHAUST PARTICULATE—SUMMARY

No. obser- vations	Operating condition .	1400 <i>I</i>	. 1800 <i>C</i>	1800 N 1/2*
7	Weight concentration, mg/m ³ Rate, mg/min	75·3 47·8	72·5 55·6	33·3 28·6
_	mg/cm³ fuel	6.3	5.4	1.3
7	Number concentration, 10° particles/cm³	199	185	682
	Rate, 1019 particles/min	12.6	14.2	58-3
	1012 particles/cm3 fuel	1.6	1.4	2.6
1	Specific surface, m ² /g	28.1	37.5	50.0
	Specific surface concentration, m2/m2	2.1	2.7	1.7
	Rate, m²/min	1.3	2.1	1.4
	m²/cm³ fuel	0.18	Õ·19	0.06
16	Bulk density, g/cm ²	0.12	0.12	·0·10
	Particle projected area diameter			
	Arithmetic mean size, A	860	860	830
	Geometric mean, A	62.0	60.5	21.0
3	Free acidity, micromole/min	5	8	5
-	micromole/cm³ fuel	ŏ.8	ŏ·8	ŏ·2
* 3.6	b.h.p.	0.0	V 0	0.77

Platinum shadowed and unshadowed photomicrographs offered a startling contrast (Fig. 1). Under shadowing conditions an entire unidentified second family of material was made visible which was not included in sizing and counting data reported. The particle height to diameter ratio was about 1:4, an aspect ratio produced by hydrocarbon oils.

Spectrographic analysis of the inorganic portion of particulates, which comprised 55-60 per cent of total particulates 18, demonstrated that about 98 per cent by weight was carbon. The chief ingredients of the non-carbon fraction were silicon, iron and zinc. Traces of aluminium, nickel, calcium, barium, as well as other metals were detected. Emission rates of iron and zinc at the 1400 I operating condition were 3.6 μg/m³ and 2.6 μg/m³, respectively. A dilution factor of approximately four would reduce these emissions to average ambient air concentrations.

BOOK REVIEWS

PEOPLE AND THEIR LAND

Population Growth and Land Use

By Colin Clark. Pp. 406. (London: Macmillan and Co., Ltd.; New York: St. Martin's Press, Inc., 1967.) 70s. net. STUDENTS concerned with problems of population growth and the result of population pressure on land use will be familiar with most of the arguments, data and methods in Colin Clark's new book, though previously they would have had to search far and wide for some of the material. Much of the book's value lies in the way the author has brought together such a mass of material, strung it on a tenuous thesis and compressed it to a mere 400 pages. A measure of the range of interests which the book covers is that it begins with measuring human fecundity and ends with land values in Chicago; yet there is a line of enquiry, sometimes more implicit than explicit, which firmly links them, and this has been central in Dr Clark's research during the past twenty years. He is always concerned with the human condition, the necessity to refine our tools of analysis and the need to see problems in economic terms. The reader is led successively through the intricacies of the reproductive capacity of human beings, problems of survival and growth, history of population growth, the relationship between this and food and fertility, sociology of reproduction, economics of growth, locational analysis and finally urban land values. The author acknowledges his debts to many fields of study and makes only modest claims for this volume as a "preliminary attempt to survey the range of material"; but there is no doubting his deep appreciation of the problems and the need to find immediate answers.

In addition to providing so many statistical methods of collating data Clark can be provocative and stimulating. His ideas about world hunger and his estimates of how it could be met make an interesting chapter. He is particularly critical of the FAO for giving a desperately pessimistic slant to world hunger by setting too high a nutritional standard. He says, "if the F.A.O. were disbanded and a fraction of its revenue devoted to the universities and private institutions where real research is being done the world would be better off". He has convincing arguments for modifying the standard, but his estimate of what the world can support is probably too generalized a picture, and in any case depends on either a redistribution of population or a system of exchange so radical that it remains an ideal. His world total of 47 billion by western standards is probably optimistic, but at least his arguments for the possibilities of meeting growing needs rather than of limiting population are challenging.

Many of Clark's views are controversial in spite of being asserted as fact. Whether medical improvements began to make discernible changes as early as 1750 is debatable. It was surely the end of the nineteenth century before the effects of medicine were radical and massive enough to affect population changes very markedly. The increased food production and the opening up of new food producing areas in the nineteenth century surely played a part in the earlier changes. Nor would everyone accept the constant implication that population increases were the prime cause of technological innovation—often it may well have been the reverse.

The book is most interesting when views such as these are being argued, though often one would wish Clark to

justify them more fully. The erudition and scope of the references are impressive—as is the absence of reference to British workers in these fields—the pace is sometimes furious, but one could wish for a more coherent statement of the central theme. The final paragraph hangs tantalizingly in mid-air, for the book has no conclusion. The greatest value of the volume is the way in which it brings together such a diverse mass of data and techniques concerning man and his demands on the land. Students of economics, sociology and geography will be indebted to Clark for this service.

EARTH DISCUSSED

Debate About the Earth

Approach to Geophysics through Analysis of Continental Drift. By H. Takeuchi, S. Uyeda and H. Kanamori. Translated by Keiko Kanamori. Pp. 253. (San Francisco: Freeman, Cooper and Co., 1967.) \$4.50.

This is a surprising book in several ways. Perhaps the pleasantest surprise is its simple readability. The authors have spared no pains to simplify every concept and argument. Comparable care has obviously been given to the design of the illustrations. An easier and more effective introduction to the current and amazing interpretation of the history of the Earth would be difficult to imagine.

The book is primarily a history of the theory of continental drift. But it is much more than that. geophysicists who wrote it found it necessary to digress rather deeply into the fundamentals of the Earth's magnetism and its thermal history. Necessary, too, were considerations of the origin of the Earth, its internal structure, the sources of its heat and the inferred mechanics of the thermal convection within its solid mantle. Into these fundamentals are woven the diverse pieces of pertinent evidence derived from palaeontology, oceanography, palaeoclimatology, and the exciting postwar discoveries by the geophysicists that bear on the most important properties of the Earth. In all this, the authors are commendably objective. Yet, to use one of their phrases, "the discerning reader" will sense their conviction that extensive drift of the continents since the Jurassic is the only satisfactory interpretation. In the light of what has since been learned about the migration of north-south belts of magnetic anomalies east and west from the mid-Atlantic ridge and the extraordinarily high heat flow and the young deposits of metals in the deepest part of the Red Sea trench, their belief seems to have been well founded.

Many readers will derive satisfaction from the way the authors show the necessary interdependence of geophysics and such disciplines of Earth science as oceanography, palaeontology, glaciology, climatology and rock magnetism. It seems, however, and perhaps only because I am a geologist, that a more important role might have been ascribed to geology. It is not very sure-footed, for example, to match mountain ranges end to end without the kind of understanding of them that comes from years of systematic mapping. Likewise, the essentiality of the understanding that petrology brings to the process of discriminating between suitable and questionable rocks for magnetic studies might have been enlarged on without unduly lengthening the text. But these are quibbles. The book makes the significant point, and makes it well, that ideas and evidence from many disciplines are essential to the solution of problems in Earth history.

Fascinating and valuable also are the ways these geophysicists have shown how a theory may be born and what the originator had in the way of facts to spark the idea. They also show what the originators lacked and, in the perspective of later knowledge, what they missed or misinterpreted.

Quite apart from their authoritative review of the Earth's history, the authors have captured much of the fun, the excitement, the doubts, the frustrations and the satisfactions of scientists who devote their lives to unravelling one aspect or another of the Earth's fascinating Having so subtly woven this human interest into the history and development of one of the boldest theories ever to come true, they should not be surprised to find, in the years to come, that they have drawn into the fraternity of Earth scientists many able young minds.

Debate About the Earth will be stimulating to a broad spectrum of students, and it will be useful to the professional geologist as a means of catching up with important and startling developments in the fundamentals of his science. The authors obviously enjoyed a happy relationship with the publishers. W. H. Bradley

NEW PHYSICS SUMMER SCHOOL

Recent Developments in Particle Physics

Edited by Michael Moravcsik. (Proceedings of the First Pacific International Summer School in Physics, August 1965.) (Nuclear Physics, Vol. 3.) Pp. viii+263. (New York: Gordon and Breach Science Publishers, 1966. Distributed in the UK by Blackie and Son, Ltd.)

THE University of Hawaii at Honolulu has now joined the ever expanding host of institutions which sponsor a vacation school or institute in some advanced area of research. They should not find much difficulty in recruiting the lecturers, but the student body is likely to remain confined to the Pacific seaboard of the United States. Thus the printed version of the lecture notes will be all the more valuable in Europe.

Proceedings of the first school in 1965 contain notes on "Particles and Cross Sections in a Theory of Local Observables", by R. Haag; "Spontaneous Symmetry Breaking and Related Problems", by H. Miyazawa; Breaking and Related Problems', by H. Miyazawa; "The Algebraic Description of Hadron Matter and its Observational Implications", by Y. Neeman; "Lectures on Bootstraps", by F. Zachariasen; "The Bootstrap Theory of Symmetry Breaking", by S. Frautschi; and "The Non-Dynamical Structure of Particle Reactions", by M. Moravcsik. These are all self-contained, concise expositions, a few overtaken by more recent developments. The most valuable are those by Haag, Miyazawa and Moravcsik. Zachariasen gave the same lectures later that year in Vienna and they have appeared in print before. By the way of preface there is a most amusing and yet convincing apologia for this kind of school by the director, M. Moravcsik.

The volume is a paperback and the price seems excessive. S. ZIENAU

SEMICONDUCTOR SURFACES

Electrical Properties of Semiconductor Surfaces By Daniel R. Frankl. (International Series of Monographs on Semiconductors, Vol. 7.) Pp. xv+310. (Oxford, London and New York: Pergamon Press Ltd., 1967.) 84s. net.

THE extent to which the electrical properties of a semiconductor are dependent on the physical and chemical conditions of its surface has been the subject of much experimental study during the past twenty years, largely prompted by the technical requirement to control and stabilize the performance of semiconductor devices. There have been corresponding advances in theoretical understanding, and much previously empirical knowledge has now been rationalized, leading to useful insight and prediction.

The literature of research on semiconductor surfaces is widely scattered except for the proceedings of topical conferences and symposia, so that the appearance of this up to date text is specially welcome. The book succeeds in its aim of being largely self contained by presenting a thorough treatment of the theoretical background necessary to interpret the experimental data. The first two chapters discuss the equilibrium distributions of electrons and ions in bulk intrinsic and extrinsic semiconductors and in their surface space-charge layers. The next chapter deals with non-equilibrium conditions arising from illumination or carrier injection and considers both the final steady state and the relaxation spectrum. The fourth chapter treats field effects in great detail as befits the experimental importance of the topic, and the related theory is competently and critically presented.

The second half of the book is devoted to surface preparations and to the surface states resulting from them. There is shown to be little relation between observed surface states and those derived from the idealized theoretical models of Tamm and of Shockley. Experimental data are presented in considerable detail together with descriptions of methods of measurement and interpretation. Germanium and silicon receive by far the greatest attention as would be expected from the extensive study already devoted to their bulk properties which is a prerequisite for an understanding of the surface data. The available fragmentary data on GaAs, InSb, ZnO, CdS and PbS are also collected.

This book conveys the impression throughout of being well organized and critically written. It will be useful to research workers both as a text and a reference. bibliography is copious and continues through 1966. The style is eminently readable, but it can only be a matter of conjecture whether the excessive use of commas should be attributed to the author or to an enthusiastic copy editor. Misprints are few and when they occur in the equations they are readily corrected by the alert reader.

R. E. Burgess

RIGOUR AND THE CALCULUS

Differential and Integral Calculus

By Friedhelm Erwe. Translated by B. Fishel. Pp. x+494. (Edinburgh and London: Oliver and Boyd, Ltd., 1967.) 57s. 6d. net.

THERE are many books on the differential and integral calculus. What justifies the appearance of another one? The present book differs from many in the rigour with which the subject matter is developed. It is not a collection of recipes and formulae, deduced largely by an appeal to intuition or experience of the physical world. Instead, it is "pure" from the start, and it is a long way to the introduction of the calculus. Continuity and differentiation are introduced only after ninety pages of preliminary material about real numbers and infinite processes. After that there is a careful development of the usual topics covered in a good course on the differential calculus. This is followed by a fairly easy chapter on the elementary functions. Integration is not the next topic to be treated. Instead, the author proceeds to a rigorous discussion of the differential calculus in the case of two or more variables. This discussion includes a long section on curves, and the definition used for a curve "admits entities which defy the possibility of geometrical visualization". The section closes with a statement of the Jordan curve theorem, and it is something of an anticlimax for us to learn that "its rigorous proof goes very deep and because of its length we shall have to omit it". Of course, the reason is that the proof lies buried in topology, and that is another story.

The last two chapters deal with integration. The first, relating to functions of one variable, covers the usual topics. But the second contains some new material, including a discussion of the parts of algebraic topology which enter into the formulation of the main results on the integration of differential forms. The book, oddly enough, concludes with a down to earth section on "the calculation of content, surface area, centroid and second moments".

From this brief survey it is evident that the book is not for the applied mathematician or the engineer. But it is an exciting book for the student of pure mathematics, and its method of approach is most valuable for anyone who hopes to do postgraduate research in mathematical analysis. L. S. GODDARD

ADVANCES IN POLYMER SCIENCE

Stereoregular Polymers and Stereospecific Polymer-

Edited by Giulio Natta and Ferdinando Danusso. (The Contributions of Giulio Natta and his School of Polymer Chemistry.) Vol. 1: Pp. xxii+1-466. Vol. 2: Pp. xx+467-888. (Oxford, Lendon and New York: Pergamon Press, Ltd., 1967.) 315s. net per set of two volumes.

Heteroatom Ring Systems and Polymers By H. R. Allcock. Pp. xi+401. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1967.) 132s.

THE announcement on December 11, 1954, by Professor Giulio Natta and his co-workers of the synthesis of a new class of polymers, obtained by the polymerization of alpha-olefins and with an exceptional regularity of structure, opened up an immense field of research which has brought remarkable fruits to both polymer science and to industry. In recent years the interest in the subject of stereoregular polymers and stereospecific polymerization has increased steadily and development of this subject continues. It is thus of some significance to have collected together in a single work the papers of those researchers who made these discoveries. Apart from its historical interest, this collection is very useful to scientists working in this field. Many of the original papers, which were published in Italian or in a language other than English, are translated in Stereoregular Polymers and Stereospecific Polymerizations. The first two volumes comprise the 170 papers, in chronological order, submitted for publication, from the discovery of stereoregular polymers (March 1954 to 1959 inclusive). All the important papers and reviews are unabridged but the others are reported as abstracts.

Among the papers will be found the first announcement of the discovery and the description of the first syntheses and industrial production of stereoregular polymers of alpha-olefins and diolefins. Other papers describe the kinetics and reaction mechanisms, the study of the structure of stereoregular molecules, of their properties in solution and in the solid state, and the industrial application of the polymers. The new polymers described in the pericd covered by these volumes were predominantly hydrocarbons. It is the editors' intention to publish the corresponding works on non-hydrocarbon monomers and polytactic polymers in subsequent volumes.

Another branch of chemistry in which there has been striking advances in recent years is that of heteroatom ring systems and polymers, particularly those in which the skeletal systems consist of silicon, phosphorus, sulphur, aluminium or carbon, bonded to oxygen, sulphur or nitrogen. The impetus to this subject has been provided by the requirements of aerospace technology for unusual polymeric materials, and in particular for materials of high thermal stability. The series of compounds such as

the siloxanes, phosphazenes, borazenes and s-triazines have received considerable attention, and in the second book, Heteroatom Ring Systems and Polymers, an attempt has been made to present a unified picture of the very wide and diverse subject of heteroatom systems. The first part of the book (first four chapters) is devoted to the general and theoretical background of the subject. The second part (fifth to seventh chapters) deals with the fundamental chemistry of these compounds and the final section (eighth chapter) is concerned with the high polymer chemistry of hetero-compounds.

The book is not devoted predominantly to the "inorganic concept" and this particular aspect of the subject is considered as part of the more general chemistry of these compounds. The general approach of the authors is a comparative one and the different heteroatom systems are compared with respect to bonding theory, aromaticity, ring-polymer equilibration, synthesis, polymerization, reactions and polymer chemistry. References up to the early part of 1966 are included in the body of the book and some important papers which appeared later are reviewed in an appendix. A second appendix contains a valuable compilation of bond angles and bond length for heteroatom compounds.

The book is a most excellent introduction and review of a new and important branch of chemistry and will be of value to the inorganic, organic and polymer chemist.

C. E. H. BAWN

CYCLOBUTADIENE AND RELATIVES

Cyclobutadiene and Related Compounds

By M. P. Cava and M. J. Mitchell. With a Chapter on Theory by H. E. Simmons and A. G. Anastassiou. (Organic Chemistry: a Series of Monographs, Vol. 10.) Pp. xiii+503. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1967.) 176s.

EVER since 1865 when Kekulé put forward the cyclic structure for benzene, chemists have been interested in the preparation of homologues of this compound in order to find out whether or not they possess an aromatic character. The next higher homologue of benzene, cyclo-octatetraene, was synthesized by Willstätter in 1911, but the lower homologue, cyclobutadiene, proved to be much more elusive. Despite the discouraging predictions of molecular orbital calculations an ever increasing number of chemists are making contributions to the field of cyclobutadienes and related compounds. Cyclobutadienes have been postulated, with varying degrees of probability, as transient intermediates in several reactions and some very elegant and sophisticated methods have been used to try to prove their existence. The most compelling evidence for the successful synthesis of cyclobutadiene itself was provided by Watts, Fitzpatrick and Pettit in 1965.

The history of attempts to prepare benzocyclobutadiene and biphenylene is also of great interest. Finkelstein was the first to prepare benzocyclobutadiene (as a transient intermediate). He also made the first derivative of biphenylene, namely 5-bromobenzo[a]biphenylene. Actually Finkelstein himself did not elucidate the structure of the biphenylene but his work was repeated and enormously extended by Cava and his co-workers. therefore very appropriate that Cava and Mitchell should write an account of cyclobutadiene and related compounds.

The quest for stable derivatives of cyclobutadiene has led to the preparation of many novel types of small ring compounds and to the discovery of many new reactions. According to the preface: "The aim of this monograph is to present in readily accessible form all of the information available on four-membered carbocyclic compounds having only trigonally hybridized carbon atoms in the ring". Thus there are chapters on cyclobutadiene: the cyclobutadiene-metal complexes; cyclobutadiene divalent ions; cyclobutadienequinone; methylene analogues of cyclobutadienequinone; benzocyclobutadiene; benzocyclobutadienequinone; methylene analogues of 1,2-benzocyclobutadienequinone; higher aromatic analogues of benzocyclobutadiene; biphenylene; benzobiphenylenes; and theoretical aspects of the cyclobutadiene problem. The monograph includes all relevant material published up to January 1, 1964, and there is an appendix containing abstracts of papers published in 1964 and 1965. In addition to published work much information has also been extracted from unpublished theses. The text is excellently written and is profusely illustrated with formulae, diagrams and tables.

The authors have admirably succeeded in their task and the book will be of great interest and value to workers on carbocyclic and on aromatic polycyclic compounds. It will be an essential work of reference for specialists in the field of four membered unsaturated rings and their benzo derivatives.

J. F. W. McOmie

CHEMISTRY OF ALKALOIDS

An Introduction to the Alkaloids

By G. A. Swan. Pp. viii + 326. (Oxford and Edinburgh: Blackwell Scientific Publications, 1967.) 63s. net.

THE problems facing an author who wishes to write an introduction to the alkaloids "suitable for advanced undergraduate and postgraduate students or for others wishing to begin a study of the subject" are daunting indeed. To make a reasonably comprehensive selection from the many classes of alkaloid, to include sufficient detail and thus avoid a sense of remoteness but at the same time to give a satisfactory general picture—these are just a few of the difficulties to be overcome. The present author has tackled these and other problems in a straightforward way and has produced a book which is instructive, up to date, comprehensive and extremely readable. Apart from an introductory chapter and a final chapter on biogenesis, the main body of the book is devoted to a description of the major classes of alkaloid, illustrated with carefully selected examples. The historical background is often described and accounts of classical degradative and synthetic work are complemented by numerous illustrations of the application of modern physical techniques such as ultraviolet, infrared, nuclear magnetic resonance and mass spectroscopy to problems of structure elucidation.

Aspects of the pharmacology of the alkaloids are also included and give added interest to the purely chemical sections.

The final chapter on biogenesis is up to date and very clearly written. The author has shown (for example, in the section on indole alkaloid biogenesis) how biogenetic studies can help to clarify and rationalize the relationships between alkaloids of apparently diverse structural types.

In a book of this nature, it is inevitable that some errors should have crept in—these, however, are very few in number and are usually of minor importance (for example, the formula for chaksine, page 275, which lacks a methyl group). Nowadays, however, when so many publications of this type show obvious signs of having been written in great haste and with little thought, it is a real pleasure to come across one in which the author has combined experience, careful planning, accuracy and style, to produce a book which fully accomplishes the intentions quoted at the beginning of this review.

A book of this kind has been long needed and this volume can be thoroughly recommended (especially in view of the very reasonable price) to everyone interested in alkaloid chemistry, specialists and non-specialists alike.

D. H. G. GROUT

WORLD KEY TO ANGIOSPERMS

Key to the Families of Flowering Plants of the World By J. Hutchinson. Revised and enlarged for use as a supplement to The Genera of Flowering Plants. Pp. vii+117. (Oxford: Clarendon Press; London: Oxford University Press, 1967.) 30s. net; paperback edition 18s. However controversial Dr John Hutchinson's well known system of classification of flowering plants might be, the key to families included in the two editions of his Families of Flowering Plants has proved to be of outstanding value to botanists throughout the world. This latest book is simply a revised and rearranged version of the family key included in the 1959 second edition. The author intends it to serve as a complement to the most ambitious yet of his publications, The Genera of Flowering Plants, of which two volumes have so far been published in 1964 and 1967, respectively. There is no doubt that it will be widely used in the field and herbarium as a working key quite independently from the Genera or any other works. As the author says in the preface, "by means of this key it should be possible to determine the family of most of the flowering plants to be met with on a day's march in any part of the world, from the north and south poles to the equator or from Greenland's icy mountains to India's coral strand".

The book consists almost entirely of the keys. A short glossary is appended and there are two pages of diagrams illustrating terms used in the keys. There are separate keys to the Dicotyledons and Monocotyledons. The Dicotyledons are divided into thirty-two artificial groups, a larger number than in the *Families*, because the main ones are subdivided into smaller units so as to ease the task of identification. Many of these smaller groups are made on the basis of the presence of opposite or alternate leaves. Although the keys are deliberately artificial, Hutchinson cannot refrain from adding that alternate leaves are usually a more primitive character and opposite leaves more advanced.

A disastrous error occurs on page 102 when about half the key to group 1 of the Monocotyledons (about twentytwo lines to judge by the key on page 528 of Vol. 2 of The Families of Flowering Plants) is omitted, so that ten families (Typhaceae, Sparganiaceae, Lemnaceae, and so on) cannot be run down.

Mechanically the keys are good and the contents usually clear. They are not, however, always dichotomous: three or four contrasting leads are common—quite unnecessarily so in most cases—and are often confusing. There are few misprints but seldom significant, except perhaps "Leaves compound of 1-foliolate, pellucid-punctate" on page 14. Another that will baffle foreign readers is "often healthy' plants" in the key to Ericaceae. The punctuation is careless in many places and should be revised in any reprint that is issued.

The keys as a whole represent an intellectual achievement of a very high order. It is difficult to imagine any competing versions being offered in the future, when, in any case, alternative methods of preparation and presentation of keys using electronic data processing will be available. Even today, it would be valuable to have the information given in Hutchinson's key available as a set of punched cards.

The brief glossary is somewhat scrappy and the definitions are often over-simplified: for example, "monoecious, unisexual flowers on the same plant"; "embryo, rudimentary plant still enclosed in the seed"; "pollen, the powdery contents of an anther (the male element of the flower)". It is difficult to believe that any serious user of the key will need to consult such an elementary list. It could well be omitted in a further edition.

Hutchinson's Keys will be a deservedly popular work, and both he and his publishers are to be commended for making it available as a separate and relatively inexpensive book.

V. H. HEYWOOD

OBITUARIES

Sir John Cockcroft

JOHN DOUGLAS COCKCROFT, who died on September 18, was born in 1897 at Todmorden, the son of a cotton manufacturer. He was one of five sons, three of whom entered the family business. Of strong physique, he played games well and loved hill walking and sports of all kinds. He showed an early interest in mathematics and physics during his education at Todmorden Secondary School. He won a scholarship to the University of Manchester at the age of 17 and began to study mathematics there, but the year was 1914 and for the next four years he was on active service in the Royal Corps of Signals and later in the Royal Artillery.

In 1919, after the war, Cockcroft returned to Todmorden and decided to become an electrical engineer. He became a student of Miles Walker at the Manchester College of Technology and a college apprentice at Metropolitan-Vickers, Ltd. Rutherford was at that time working at the University of Manchester but he was shortly to leave for Cambridge. In his years at Manchester, Rutherford had established the nuclear theory of the atom through his studies of a-particle scattering and had gathered around him a brilliant band of young colleagues-Geiger, Marsden, Nuttall, Mosely, Bohr, Chadwick, Robinson, Andrade, Darwin-giving to Manchester the excitement and challenge of entering a new world. Rutherford had demonstrated for the first time that certain light atomic nuclei could be disrupted by the impact of a-particles from radioactive substances; this moment, when Ra-C α-particles were shown to disrupt nitrogen nuclei and eject fast hydrogen nuclei, could perhaps be regarded as the birth of the new and vast subject of nuclear physics. It is not surprising, in retrospect, that the attraction of Rutherford's work drew Cockcroft to Cambridge, first to resume his mathematics and then to join Rutherford at the Cavendish Laboratory. There, in 1924, he was put to work in the laboratory attic by Chadwick, to practise α -particle and proton counting, to produce what then passed for a high vacuum and to make gold leaf electroscopes to measure γ-ray intensities.

After this apprenticeship Cockcroft was diverted to make use of his electrical engineering in helping Kapitza install an alternator which was to be shortcircuited through coils, designed by Cockcroft, to generate magnetic fields of up to 300,000 gauss. Rutherford, in his presidential address to the Royal Society on November 30, 1927, urged "the development of sources of atoms and electrons with an energy far transcending that of α and β particles from radioactive matter" use in scattering and disrupting studies of target nuclei. Allibone started work on electron acceleration and his success in operating accelerating tubes at 300 kV led Cockcroft to think seriously of accelerating protons with similar objectives in view. In November 1928, Gamow paid a timely visit to the Cavendish Laboratory and in a lecture expounded his quantum theory of atomic disintegration according to which a finite probability existed of a-particles penetrating the potential barrier around a Cockeroft calculated that, according to this theory, 300 kV protons should produce about 2×10^6 d.p.m./min/m.amp of protons impinging on boron. He decided to try accelerating protons at a steady voltage of 300 kV and, with E. T. S. Walton, installed a 250 kV transformer, built a voltage doubling rectifier circuit for 300 kV and used this to drive an accelerating tube with a high voltage canal tube as a proton source.

A wide range of targets from lithium to lead were examined under the proton beam but no gamma radiation (arising from proton capture) was observed. enforced move to another laboratory at Cambridge prevented a search for α-particle emission and led them to build a new apparatus for 500-600 kV using a voltage quadrupling circuit of a modified Greinacher type. This took six months and the main problem was that of retaining a high enough vacuum. The low vapour pressure greases and 'Plasticine' and the oil diffusion pumps developed by C. R. Burch at Metropolitan-Vickers played a vital part in the work. After long proving tests and running-in experiments, a lithium target was bombarded with 2 m.amp of protons and they observed large numbers of bright scintillations on a zinc sulphide screen placed outside the apparatus. made it plain that α-particles, and not protons, were responsible. The scintillations increased fortyfold as the accelerating voltage was increased from 126 to 250 kV. This was the first occasion on which nuclear reactions were achieved using artificially accelerated particles, and, according to Cockcroft's account, "there was a certain amount of fuss made by the Press after Rutherford made the announcement of the discovery at a Royal Society meeting and Rutherford told the Press that the idea of obtaining power from nuclei was 'all moonshine' '

The scale of the Cockeroft and Walton experiment, which Cockcroft's electrical engineering knowledge and expertise made possible, took nuclear physics into a region in which the work was beyond the scope of the individual physicist. Their work, together with that of Lawrence at Berkeley, began an age of accelerating machines in nuclear physics typified by the Brookhaven Cosmotron, the Berkeley Bevatron, the CERN and Dubna machines and the Rutherford High Energy Laboratory NIMROD. The work of Cockeroft and Walton, the first in the field to be successful, marks in retrospect a watershed between classical and modern nuclear physics. For their work Cockcroft and Walton were jointly awarded the Nobel Prize for Physics in 1951. In the same year as the Cockcroft-Walton experiment, Chadwick, using the simple and elegant methods of the age that was now to end, proved the existence of the neutron; this event was also of great significance and led directly to the studies of neutron-nuclei interactions that gave rise to the discovery of nuclear fission in 1939.

In 1934, after Kapitza's return to Russia, Cockeroft

took over the direction of the Royal Society Mond Laboratory and he participated in the various developments at the Cavendish Laboratory which led, in 1936. to the construction of a new high voltage laboratory under the leadership of Dee. In particular, Cockcroft was responsible for the design and construction of the 37 in. Cavendish cyclotron, one of the first two in Britain and which operated in 1939 just before the war. Early in 1938, however, Cockcroft was told about the secret developments which had taken place in radar methods of detecting the presence and position of aircraft. informant was Tizard who, together with many others already involved, saw that in the event of war the effectiveness of radar would depend on there being large numbers of trained experts. Cockcroft, who was a leading member of the Cavendish Laboratory, had just the right background in science and electrical engineering to appreciate not only the problems but the way in which they could be solved.

Cockcroft paid several visits to Bawdsey Manor on the Suffolk coast where the Air Ministry and War Office radar research teams were working, and saw one of the chain of long range stations that was already working routinely. He also saw equipment for airborne ship detection, gun laying and other applications of radar. He quickly fostered contacts between the Cavendish and Bawdsey Research Stations; Dee, Feather and Ratcliffe were initiated and Lewis, who was already working on pulse techniques, began to spend some of his time at Bawdsey. During the following months Cockcroft spread a secret net not only at Cambridge but in other universities, and recruited in an informal way more than eighty young academic scientists. They were sworn to secrecy and agreed to go out to the various stations around our coasts to learn the details of the circuits so that they could help to keep the equipment up to the peak of performance. In August 1939 the teams of scientists set out and Cockcroft, leading one of the parties, went to the radar station at Rve.

The expected air attacks on the United Kingdom did not materialize and after a few weeks Cockcroft and his party were sent to Bawdsey Manor to help Butement with an experiment using a 200 cm coast defence set in spotting a submarine allocated by Admiral Sir James Shortly after this successful experiment, enemy submarines began to use the channel between the Shetlands and the Orkneys. Somerville appealed to Watson-Watt for some radar equipment to help in intercepting them. Watson-Watt consulted with Cockcroft, who agreed that he and his team, which included Ratcliffe, Ashmead and Firtel, should organize and take part in the construction (with the help of Messrs Pye and Metropolitan-Vickers), the siting, the installation and the running of several stations.

The anti-submarine stations were constructed and became operational during the winter of 1939-40; this was a remarkable achievement in view of the difficulties of transport to the island sites and the wild weather which hindered the installation and testing. The desired detection of submarines was achieved, but the ability of

the 200 cm radar to see low flying aircraft heading for Scapa Flow proved even more important.

The use of 200 cm sets to detect low flying aircraft was already known but none had been installed in the main radar chain because all the effort had been concentrated on the 13 m early warning sets. In the autumn of 1939 much of the mine laying in coastal waters was being carried out by enemy aircraft at minimum height. There was a desperate need for two installations to cover the Thames, and Cockcroft, already committed to making equipment for the Hebrides, was asked to provide two extra stations. Pye Radio made the receivers and aerials, and assisted in the installation; gun laying radar transmitters were modified at Metropolitan-Vickers to operate on 200 cm wavelength and by the beginning of December 1939 the first station became operational.

From the beginning of radar development it had been clear that many problems would be solved, particularly concerning airborne installations, if sufficient power could be generated at wavelengths of a few centimetres, enabling narrow beams to be produced by small aerial systems. In 1939 Brundrett, who was then chairman of the Inter-Services Committee for Co-ordination of Valve Development, formalized the requirement by placing a contract with Professor Oliphant at the University of Birmingham. The cavity magnetron, produced by Randall and Boot, was so successful that it was judged the most significant item when Tizard, with Cockcroft as his deputy, disclosed it to the United States on the famous mission in 1940. Cockcroft had followed the development and early application work using the cavity magnetron, and on his return from the mission was appointed chief superintendent of the Air Defence Research and Development Establishment at Christchurch, where he supervised the work on 10 cm coastal defence equipment.

While Cockeroft was in charge at ADRDE he fostered many new ideas; for example, Bateman and Shine devised the anti-aircraft proximity fuse which was so effectively used against the VI weapon and in the Pacific war; and Eastwood, Oxford and Chick developed searchlight control by radar. Throughout the radar war, Cockeroft was always willing to take on the heaviest loads of the moment and there is no doubt that he played a vital part.

The early discussions on the possibility of developing an atomic bomb, including the deliberations of the famous MAUD Committee and Cockcroft's involvement in them, have been admirably described by Mrs Gowing1. 1944 he was sent to Canada to become director of the Anglo-Canadian Atomic Energy Laboratory in Montreal. It had been agreed at an earlier stage that, in the circumstances of the war, only the United States could provide the tremendous scientific and manufacturing resources required to make fissile material. Extraordinary efforts were made to achieve secrecy and inevitably key decisions were made in America by Americans. For a time, relations between the United States and Britain on the atomic bomb project became strained and the Anglo-Canadian team in Montreal began to feel isolated. Cockcroft's presence in Montreal and the support he received from Chadwick in Washington gradually effected an improvement in relations with the Americans and under his calm but energetic guidance the laboratory, with its mixed British, Canadian and French staff, acquired a real sense of purpose. The design and development of the 10 MW heavy water reactor were vigorously pursued, a site was selected on the Ottawa River, near Chalk River, Ontario, and construction began in 1946. Chemical processes were also developed for recovery of uranium from the irradiated fuel as well as for separation of uranium-233 from irradiated thorium oxide rods in the reflector. Cockeroft and many of the staff moved from Montreal to the new town site at Deep River towards the end of 1945. By the time he left Canada in the autumn of 1946 the reactor was almost completed, the laboratories were fully

occupied and the town had become a settled community. The NRX heavy water reactor later proved to be one of the most valuable research reactors in the world and became the prototype for further successful developments in Canada.

Simultaneously with the development of the programme in Canada, much thought and effort was devoted to British requirements. It was decided that the British production programme, like that of the United States, should be based on graphite moderated reactors, and the essential design features of a graphite moderated research reactor to be built at Harwell were worked out in Montreal. During this period the pressure on Cockcroft was extremely heavy. He was constantly travelling between Chalk River and Montreal, London and Washington, and besides all the problems of three widely spaced laboratories, he had to contend with a very high rate of staff turnover when people left at the end of the war and new recruits had to be brought in to replace them.

Cockcroft was appointed director of the new Atomic Energy Research Establishment at Harwell while he was in Canada. He was by now thoroughly familiar with the problems of atomic energy and was able to push the work ahead without hesitation. From the beginning he ahead without hesitation. insisted on the minimum of formality and red tape and secured from the Government a large measure of autonomy for the Establishment. Developments at Harwell have already been described2,3 and only a brief account of those

intensively active years need be given here.

The first task of the Establishment was to provide the information required to enable the Industrial Group to build and operate the atomic energy production plants at Under Cockcroft's guidance, progress was rapid; GLEEP and BEPO, the first reactors to be built in western Europe, began operating in 1947 and 1948, respectively, and the first particle accelerator, a 5 MV Van de Graaff machine, came into service in 1947. Research and development on the chemical separation process to be used at Windscale depended heavily on the Chalk River Laboratory until the new radiochemical laboratories opened at Harwell in 1949. By 1952, the initial development work had been successfully completed although much remained to be done, especially in connexion with the new diffusion plant at Capenhurst. Cockcroft then turned his attention to the development of civil nuclear power. He arranged meetings between representatives of the power industry, the Industrial Group and Harwell staff known as the Harwell Power Conferences which laid the foundations for future cooperation with industry. An early outcome of the work was the design and feasibility study of a carbon dioxide cooled natural uranium power reactor known as PIPPA. This study was taken up by Hinton and Owen in the Industrial Group and, after a substantial design and engineering development effort, the Calder stations were built at Calder Hall in Cumberland. This was the first large scale nuclear power station in the world and was the prototype for the MAGNOX series of nuclear stations subsequently built for the Central Electricity Generating Board. The first step in the development of another type of power reactor, the fast breeder, was taken when a zero energy experiment ZEPHYR began to operate at Harwell early in 1954. This was followed by ZEUS, which furnished the reactor physics data for the fast reactor later built at Dounreay.

It was by no means clear in the 1950s that the main reactor types had been identified which would prove to be most economic, and so several different systems were studied at Harwell in this period. These included the pressurized water, homogeneous aqueous, liquid metal and fused salt systems which were being examined in the United States, and two new schemes, one based on gaseous uranium hexafluoride and the other on a high temperature system based on graphite impregnated with fissile material. Work on pressurized water was continued in connexion with marine applications, but the other systems were dropped except for the high temperature (HTR) system.

In 1958 the idea of a joint European reactor project was considered and Cockcroft suggested that the HTR should be adopted. The OECD High Temperature Reactor Project (DRAGON) was started in 1959 at Winfrith as a result of this initiative, and has proved very successful.

Always eager to help universities to benefit from the technology and developments in government laboratories, Cockcroft entered into an agreement with two colleges of the University of London to build a large proton linear accelerator at Harwell "outside the wire" so that security restrictions need not affect collaboration between Harwell and university physicists as equal partners. This idea led to the creation of the National Institute for Research in Nuclear Science in 1957—now the Rutherford High Energy Laboratory of the Science Research Council. This was Cockcroft's own creation and the fulfilment of a dream of what he used to call a "British Brookhaven". He actively promoted international co-operation and was closely concerned in the formation and early growth of CERN, the European nuclear physics laboratory in Geneva, and he was the British representative on the council for many years.

Cockeroft also saw the potential of radioactive isotopes made in reactors for use in industry, agriculture, medicine and research, and he promoted the rapid development of techniques for producing and using them. In a remarkably short space of time a substantial international

market was developed.

The breadth and vision displayed by Cockcroft in developing Harwell from an RAF airfield into one of the great scientific institutions in the world were allied with a deep personal interest in everything that was going on. He was always insistent that basic work, on which future technology would depend, should be vigorously developed and the results published freely in the scientific literature. The basic studies ranged from solid state chemistry and physics to radiation chemistry, neutron physics and nuclear physics. In particular, he saw very early that nuclear fusion might well be a practicable power source in future years and his personal interest in the work led eventually to the setting up of the Culham Laboratory.

Harwell staff were always astonished to discover Cockcroft asking about the progress of work that he had glimpsed in a laboratory visit months or years before. The little black book, in which he noted everything requiring action or that he needed to remember, his microscopic handwriting, and the crisp terse notes, were all regarded affectionately as characteristic of this wise and modest man.

One of Cockeroft's most abiding convictions was that advancement in science, and indeed in human affairs, could only come through international understanding and co-operation. He was tireless in the arduous task of establishing international communications in the field of nuclear science and technology and in encouraging the growth of co-operation between individuals and laboratories in different parts of the world. The series of United Nations conferences at Geneva on the Peaceful Uses of Atomic Energy, and perhaps especially the first. owed a great deal to him.

In 1959, Cockcroft returned to Cambridge as Master of the new college named in honour of Winston Churchill. He accepted with enthusiasm the challenge of creating something new and fine and enduring while at the same time maintaining many of his other active interests. His life was a full one to the end.

Many colleagues have shared in the writing of this obituary. PENNEY

University News:

London

PROFESSOR R. C. TRESS, professor of political economy in the University of Bristol, has been appointed master of Birkbeck College in succession to Dr F. K. Hare.

Massachusetts Institute of Technology

Professor N. Levinson has been appointed head of the Department of Mathematics in succession to Professor W. T. Martin.

Lagos

PROFESSOR KURT SALOMON has been appointed professor and chairman of the newly created Department of Radiation Biology and Radiation Therapy in the College of Medicine.

Announcements

PROFESSOR D. GABOR has been awarded the Cristoforo Colombo Prize for 1967 by the International Institute of Communications in Genoa.

ERRATUM. Professor R. E. Davies, of the University of Pennsylvania (School of Veterinary Medicine), has written to the Editor to complain that the words "Professor A. V. Hill's Further Challenge to Biochemists" were omitted from the title of his article, "ATP, Activation, and the Heat of Shortening of Muscle", published in Nature, 214, 148 (1967). This change was made in the Nature office because the statement following the title began with the words "Prof. A. V. Hill has challenged biochemists to find whether the heat of shortening of muscle . . .". Professor Davies wishes it to be known that he considers the omitted words "by far the most important part of the title" because he wishes "to honour him [Professor A. V. Hill] by using his name in the title".

The Editor reserves the right to make changes to titles either so as to keep their length within reasonable bounds or so as to make them easier to understand, and if there is any danger of a change of meaning, authors are, of course, informed. The Editor is at a loss to know why Professor Davies has argued so strongly in favour of his original words.

CORRESPONDENCE

First AGR for Scotland

SR,—May I comment on the statements attributed to me in your article "First AGR for Scotland" (*Nature*, 216, 213; 1967)?

1. It was not I, but other witnesses, who claimed in evidence to the Select Committee on Science and Technology that replication could save 10 per cent in the cost of a second station. My views are made clear from Mr Lubbock's question (minutes 381-V, paragraph 515) to me: "I notice that you do not think very much of replication; you do not agree with the figure which has been given to us of a 10 per cent reduction for a Chinese copy of an existing nuclear station".

2. Our views on replication and improvements in design are explained at length in paragraphs 18-23 of our memorandum. The circumstances at the time of the Hunterston tender led us to adopt a policy of replication,

in line with paragraph 19.

3. In comparing Hinkley Point 'B' with Dungeness 'B', I claimed that improvement of design through competition, and not replication, brought down the price by more than 10 per cent (paragraph 516).

4. The construction-cost of Hinkley Point 'B' has been published by CEGB as £92m (£94m including gas turbines). It is misleading to compare these costs with the figure of

£87.5m announced by SSEB for Hunterston, because site conditions and the extent of supply are different.

5. Such comparisons are extremely difficult to make with any accuracy. The best estimate we have been able to make of the relative prices of Hinkley and Hunterston after adjustments for the differences in the two contracts shows a reduction of about 7 per cent for replication. There would be no such reduction for a third station.

6. We now know that our price for Hunterston was the most competitive. It follows that Hinkley, at only 7 per cent higher, must also have been very competitive. It could not have been, as alleged by some irresponsible commentators at the time, £10-£13m too high, and a "national scandal".

Yours faithfully,

S. A. GHALIB (Managing Director)

The Nuclear Power Group Limited, Radbroke Hall, Knutsford, Cheshire.

Assessing the AGR

SIR,—The terms in which you have commented on the latest Annual Report of the Kjeller Laboratory of the Norwegian Institutt for Atomenergi prompts us to seek to add to the views we have already expressed to you.

The survey was an attempt made during 1966 to prepare an economic comparison of various reactor systems. Although it represents the AGR as having slightly higher generating costs than other systems it concludes that "there is no significant difference in the power costs of the thermal reactor types for large stations or high yearly load". Examination of the generating costs given in the report shows that the scatter between reactor systems for any given reactor size is small indeed—mainly under 5 per cent. Even under conditions of competitive tender for plants much more alike than those studied in the report, offers can span a price range several times greater than this. In this study the figures are just buyers' estimates based on a variety of uncertainties:

The AGR figures are based on data supplied by the UKAEA but even so are not a proper substitute for a tender price.

The BWR figures derive from a General Electrical Company of the United States price list issued in 1964 and replaced several times since, prices having increased 20–30 per cent up to the end of 1966.

The PWR costs are based on the same BWR price list.

The BHWR costs are obtained from a computerized projection.

The CANDU costs depend on a scaling assumption applied to Canadian data.

The report emphasizes that the comparison between the various systems will be kept up to date as new data on them are obtained. In view of the comments made at the recent IAEA Symposium in London on the dangers of drawing conclusions from generalized comparisons of reactor costs, this is clearly a wise policy. In this connexion it is relevant to note that, through the medium of the British Nuclear Export Executive, we are discussing the potential in Norway for nuclear power station designs based on British and Norwegian technology with a Norwegian group comprising the Institutt for Atomenergi, Norsk Hydro, NVE and Noratom.

Yours faithfully,

E. H. UNDERWOOD
Director of Public Relations.

United Kingdom Atomic Energy Authority, London.

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Monday, November 13

INSTITUTION OF ELECTRICAL ENGINEERS (joint meeting with the Electron Microscopy Group of the Institute of Physics and the Physical Society, at the Institution of Electrical Engineers, Savoy Place, London, WC2), at 10 a.m.—Colloquium on "Electron Probe Instrumentation".

Society of Chemical Industry, Pesticides Group (at 14 Belgrave Square, London, SW1), at 5 p.m.—Dr M. Elliott: "Structural Requirements for Pyrethrin-like Activity".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 5.30 p.m.—Dr A. R. W. Broadway and Mr G. Thomas: "Single-Unit P.A.M. Induction Frequency Convertors".

INSTITUTION OF MECHANICAL ENGINEERS, THERMODYNAMICS AND FLUID MECHANICS GROUP (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p.m.—Discussion Meeting on "The Transport of Solids by Gases".

Tuesday, November 14

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 2 p.m.—Colloquium on "Design of High Frequency Transistors with Special Reference to High Power".

ZOOLOGICAL SOCIETY OF LONDON (at the Zoological Gardens, Regent's Park, London, NW1), at 5 p.m.—Scientific Papers.

INSTITUTION OF ELECTRICAL ENGINEERS (joint meeting with the Automatic Control Group of the Institution of Mechanical Engineers, at the Institution of Electrical Engineers, Savoy Place, London, WC2), at 5.30 p.m.—Mr R. G. Blake, Mr P. M. Piggott and Mr R. J. Smale: "Optimization of the Control of a Large Plant by Hybrid Computation".

University of London (at Imperial College of Science and Technology, London, SW7), at 5,30 p.m.—Professor J. T. Stuart: "Hydrodynamic Stability of Fluid Flows" (Inaugural Lecture).*

UNIVERSITY OF LONDON (at the Institute of Child Health, Guilford Street, London, WC1), at 5.30 p.m.—Dr G. F. Joplin: "The Effects of Y-90 Pituitary Implantation in Man". (Ninth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)*

University of London (at the London School of Hygiene and Tropical Medicine. Keppel Street, Gower Street, London, WC1), at 5.30 p.m.—Dr Arthur Engel: "Perspectives in Health Planning. I, Health Planning in a Changing Society". (First of four Heath Clark Lectures.)*

ROYAL STATISTICAL SOCIETY, GENERAL APPLICATIONS SECTION (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, WCI), at 6 p.m.—Mr F. E. Whitehead and Mr P. G. Gray: "The 1966 Sample Census".

INSTITUTION OF ELECTRICAL ENGINEERS, LONDON GRADUATE AND STUDENT SECTION (at the Woolwich Polytechnic, Wellington Street, London, SE18), at 6.30 p.m.—Mr D. Wilkinson: "Satellite Communications".

Tuesday, November 14-Thursday, November 16

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS and the INSTITUTION OF ELECTRICAL ENGINEERS (at the National Physical Laboratory, Teddington, Middlesex)—Conference on "R.F. Measurements and Standards".

PLASTICS INSTITUTE (at the Kensington Close Hotel, London, W8)—Conference on "Advances in Packaging with Plastics".

Wednesday, November 15

BRITISH INSTITUTE OF RADIOLOGY, and the HOSPITAL PHYSICISTS' ASSOCIATION (at the Middlesex Hospital Medical School, Cleveland Street, London, W1), at 10 a.m.—Meeting on "The Design of Counting Systems for Dynamic Studies and Uptake Measurements".

SOCIETY FOR ANALYTICAL CHEMISTRY (at the Atomic Energy Research Establishment, Harwell, Didcot, Berks), at 10.15 a.m.—Meeting on "Some Aspects of Inorganic Trace Element Analysis".

ROYAL INSTITUTION, HISTORY OF SCIENCE DISCUSSION GROUP (at 21 Albemarle Street, London, W1), at 1 p.m.—Mr D. Chilton: "X-rays—a Case History in the Immediate Application of a Scientific Discovery".

SOCIETY OF CHEMICAL INDUSTRY, FINE CHEMICALS GROUP (in the Main Lecture Theatre of the Physics Department, Imperial College, London, SW7), at 2.30 p.m.—Symposium on "The Carbonyl Group".

INSTITUTE OF NAVIGATION (at the Royal Institution of Naval Architects, 10 Upper Belgrave Street, London, SW1), at 3 p.m.—Professor Dr Hatsuzo Tani: "Manoeuvring Mammoth Ships".

ROYAL STATISTICAL SOCIETY (in the Botany Theatre, University College London, Gower Street, London, WC1), at 3 p.m. and 5.15 p.m.—Discussion Meeting on "British Official Statistics", Part 1: "Social and Medical Statistics".

UNIVERSITY OF LONDON (at the Institute of Diseases of the Chest, Brompton Hospital, London, SW3), at 5 p.m.—Dr F. J. Prime: "The Atmosphere".*

Society of Instrument Technology (at the A.E.I. Cinema, 33 Grosvenor Place, London, SW1), at 5.30 p.m.—"The Heat Motor".

UNIVERSITY OF LONDON (at the Institute of Neurology, National Hospital, Queen Square, London, WC1), at 6 p.m.—Professor R. W. Ritchie Russell and Professor P. N. Campbell: "Nucleic Acid Metabolism in Neurology—Clinical and Biochemical Aspects".*

Institute of Information Scientists (at Knightway House, 20 Soho Square, London, W1), at 6.15 p.m.—Mr A. G. A. Pickford: "An Objective Method for the Generation of an Information Retrieval Language".

SOCIETY OF CHEMICAL INDUSTRY, MICROBIOLOGY GROUP (Joint meeting with the Food Group, at the School of Pharmacy, Brunswick Square, London, WC1), at 6.15 p.m.—Dr K. Kaindl: "Irradiation of Fruit and Fruit Julees".

INSTITUTE OF FUEL (at the Central Mess, Duke of York's Headquarters, Sloane Square, London, SW3), at 6.30 p.m.—Mr T. Beswick: "Developments in Nuclear Power Generation".

Wednesday, November 15-Thursday, November 16

POWDER METALLURGY JOINT GROUP of the IRON AND STEEL INSTITUTE and the INSTITUTE OF METALS (at Church House, Great Smith Street, London, SW1)—Tenth Anniversary Meeting.

Thursday, November 16

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College London, Gower Street, London, WC1), at 1.20 p.m.—Dr R. C. Fisher: "Parasitic Insects".*

ROYAL INSTITUTION (at 21 Albemarle Street, London, W1), at 2.30 p.m.—Professor George Porter, FRS: "Molecules" (Civil Service Lecture).

SOCIETY FOR ANALYTICAL CHEMISTRY, AUTOMATIC METHODS GROUP (at the Wellcome Building, Euston Road, London, NWI), at 3 p.m.—Second Annual General Meeting, followed by a meeting on "Automatic Methods in the Fermentation Industry".

ROYAL SOCIETY (at 6 Carlton House Terrace, London, SW1), at 4.30 p.m.—Mr P. V. E. McClintock and Mr H. M. Rosenberg: "The Interactions of Spins and Lattice Vibrations at Low Temperatures"; Mr D. M. Edward and Mr E. P. Wohlfarth: "Magnetic Isotherms in the Band Model of Ferramagnetism".

LINNEAN SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W1), at 5 p.m.—Professor V. H. Heywood: "Scanning Electron Microscopy and the Use of Micro-Characters in Taxonomy (with special reference to the Classification of the Umbelliferae)"; Dr Patrick Echlin: "The 1 se of Scanning Reflection Electron Microscopy in the Study of Plant Material".

LONDON MATHEMATICAL SOCIETY (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W1), at 5 p.m.—Annual General Meeting, followed by Professor G. Higman: "Odd Characterizations of Simple Groups". (Presidential Address.)

INSTITUTE OF PETROLEUM, EXPLORATION AND PRODUCTION GROUP (at 61 New Cavendish Street, London, W1), at 5.30 p.m.—Mr J. E. Warren: "Optimization of Production—Storage-Export Systems".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 5.30 p.m.—Discussion Meeting on "Are Component Specifications being Improved?" opened by Mr R. H. W. Burkett, Mr J. D. Hinchcliff and Mr D. S. Girling.

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 5.30 p.m.—Mr G. S. Wilton, Mr T. S. Ormiston and Mr R. A. Alian: "Modern Transmission Line Maintenance".

UNIVERSITY OF LONDON (at the Institute of Child Health, Guilford Street, London, WC1), at 5.30 p.m.—Dr B. Creamer: "Paneth Cells". (Tenth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)*

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, WC1), at 5.30 p.m.—Dr Arthur Engel: "Perspectives in Health Planning. II, Statistics and Health Planning". (Second of four Heath Clark Lectures.)*

UNIVERSITY OF LONDON (at the Middlesex Hospital Medical School, Cleveland Street, London, W1), at 5.30 p.m.—Professor Bo Holmstedt: "The Use of Gas Chromatography and Mass Spectrometry in Studies of Drugs and Metabolites".*

Society of Chemical Industry, Road and Building Materials Group (at 14 Belgrave Square, London, SW1), at 6 p.m.—Mr S. G. Campbell: "Developments in the Manufacture and Application of Road and Airfield Marking".

INSTITUTION OF ELECTRICAL ENGINEERS, LONDON GRADUATE AND STUDENT SECTION (at Hendon College of Technology, The Burroughs, London, NW4), at 6.30 p.m.—Dr S. Jones: "Automatic Control in British Railways".

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN (at the School of Pharmacy, University of London, Brunswick Square, London, WC1), at 7 p.m.—Meeting on "The 'Sainsbury' Report".

ROYAL TELEVISION SOGIETY (in the Conference Suite, 70 Brompton Road, London, SW3), at 7 p.m.—Mr Quentin Lawrence: "Whither Television? a Director's Look at Television Engineering".

BRITISH INSTITUTE OF RADIOLOGY (at 32 Welbeck Street, London, W.1), at 6 p.m.—Discussion Group Meeting. 7.30 p.m.—Professor W. V. Mayneord: "Radiation Carcinogenesis" (Mackenzie Davidson Memorial Lecture).

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, WC1), at 7.30 p.m.—Laboratory Meeting. Chairman: Professor P. C. C. Garnham, FRS.

Friday, November 17

ROYAL INSTITUTION, PHOTOCHEMISTRY DISCUSSION GROUP (at 21 Albemarle Street, London, W1), at 1 p.m.—Dr F. Wilkinson: "Photochemistry of Duroquinone".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 5.30 p.m.—Dr E. Cohen: "Hall Effect Transducers".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 5.30 p.m.—Mr L. Solymar: "Josephson Junctions".

SOCIETY FOR ANALYTICAL CHEMISTRY, THERMAL ANALYSIS GROUP (at the Geological Society of London, Burlington House, Piccadilly, London, W1), at 6 p.m.—Third Annual General Meeting followed by Dr R. C. Mackenzie: "Differential Thermal Analysis—Whence and Whither?"

ROYAL INSTITUTION (at 21 Albemaric Street, London, W1), at 9 p.m.—Mr Huw Wheldon: "Television and the Arts".

Saturday, November 18

BIOGHEMICAL SOCIETY (at the Medical Research Council Laboratories, Carshalton, Surrey)—476th Meeting. Colloquium on "Toxic Substances and Brain Metabolism", and an Ordinary Meeting for the presentation of communications.

Monday, November 20

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 5.30 p.m.—Dr W. D. Humpage and Dr T. N. Saha: "Digital Computer Methods in Dynamic Response Analysis Turbogenerator Units".

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, WCI), at 5.30 p.m.—Dr Arthur Engel: "Perspectives in Health Planning. III, Mass Screening for Asymptomatic Disease as a Public Health Measure". (Third of four Heath Clark London 1988) Clark Lectures).*

SOCIETY FOR ANALYTICAL CHEMISTRY, RADIOCHEMICAL METHODS GROUP (at the Pharmaceutical Society, 17 Bloomsbury Square, London, WC1), at 6 p.m.—Annual General Meeting, followed by Dr P. G. Jeffrey: "The Application of Isotope Neutron Sources in Analytical Chemistry"; Dr K. Ansell: "Isotopic Radiation Sources for X-ray Analysis"; Mr J. Johnston: "Bremsstrahlung Methods in Industry".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

TEMPORARY ASSISTANT LECTURER IN PSYCHOLOGY—The Secretary, University of St. Andrews, College Gate, St. Andrews, Fife, Scotland (November 15).

CHIEF LABORATORY TECHNICIAN in the ZOOLOGY SECTION of the DEPARTMENT OF BIOLOGICAL SCHENGES—The Staff Officer, Portsmouth College of Technology, Hampshire Terrace, Portsmouth, Hampshire (November 17).

LECTURER (medically or scientifically qualified candidate) in the DEPARTMENT OF CHEMICAL PATHOLOGY—The Registrar and Secretary, The University, Leeds, 2 (November 18).

CHAIR OF APPLIED MATHEMATICS—The Secretary, University of Exeter, Northcote House, The Queen's Drive, Exeter, Devonshire (November 21).

ASSISTANT LECTURER (preferably with qualifications to undertake teaching and research in one of the following fields: physiology with special reference to cellular biology; population genetics) in Zoology at the University of Canterbury, Christchurch, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (New Zealand and London, November 24).

DEMONSTRATOR (nonours graduate in an appropriate biological subject) in Histology in the Department of Zoology—Professor J. M. Dodd, Department of Zoology, The University, Leeds, 2 (November 25).

HEAD (with high academic qualifications and considerable research experience) of the Envomology Section—The Secretary, National Vegetable Research Station, Wellesbourne, Warwick (November 25).

LECTURER IN STATISTICS in the DEPARTMENT OF SPATISTICS, School of Mathematics—The Registrar, The University, Newcastle upon Tyne, 2 (November 27).

LECTURER of ASSISTANT LECTURER (with postgraduate experience in the field of higher plant genetics, and preferably some interest in plant breeding) in Genetics, the Facility of Strathchyde, George Street, Glasgow, CI (November 30).

LECTURER (physiciat, preferably with theoretical or experimental research interests in lasers or plasma physics) in the DEPA

HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue.

The direct postal price per subscription for one or two copies of NATURE each week is:

*12 MONTHS (52 issues and 4 indexes)

Great Britain and Eire£14.0.0	each
United States of America(by air freight)\$48	
Canada(by air freight) \$52	
Elsewhere overseas by surface mail£14.0.0	
LIBOTATION CANADAD DA SELLEGO HILLIAM	000

(Charge for delivery by air mail on application) *Shorter periods pro rata. (Minimum three months.)

MULTIPLE SUBSCRIPTIONS

For subscribers who take more than two copies of NATURE each week these reduced annual rates are offered:

12 MONTHS (52 issues and 4 indexes)

Number of	G.B. &	U.S.A, Canada		Elsewhere	
Copies	Eire	(by air freight)		(surface mail)	
3–5 6–11 12 or more	Each £13.10.0 £12.15.0 £12.0.0	Each \$46,50 \$44,50 \$42,50	Each \$50.50 \$48.30 \$46.00	Each £13.10.0 £12.15.0 £12.0.0	

Multiple subscriptions must run concurrently. Every copy will be posted separately, and for speed of delivery each subscription can be addressed to a different individual, or department at the same address. (ZIP essential for U.S.A.)

LECTURER (preferably with experience in cellular physiology or electron microscopy) in the DEPARTMENT OF ZOOLOGY, University of Melbourne-The Association of Commonwealth Universities (Branch Office), Mariborough House, Pall Mall, London, SW1 (Australia and London, December 20).

LECTURER (with research interests in cell biology, especially its more molecular aspects) in the DEPARTMENT OF BIOPHYSICS, School of Biological Sciences—The Registrar, King's College (University of London), Strand, London, WC2 (December 31).

BACTERIOLOGIST (with an honours science degree) to prepare and standardize diagnostic reagents—The Personnel Officer, Public Health Laboratory, Colindale Avenue, London, NW9.

GRADUATE RESEARCH ASSISTANT in the DEPARTMENT OF GENETICS for a research project on the chromosomes of self healing skin tumours—The Department of Genetics, University of Glasgow, Glasgow, W2.

POSTDOCTORAL RESEARCH FELLOW for work in collaboration with Dr G. S. Park, on organic gells—The Deputy Registrar (Personnel), University of Wales, Institute of Science and Technology (Designate), King Edward VII Avenue, Cathays Park, Cardiff.

VISITING PROFESSOR; an ASSISTANT PROFESSOR; and a TECHNICAL OFFICER or PROFESSORAL ASSISTANT in the DEPARTMENT OF GEOPHYSICS—Professor A. E. Beck, Head, Department of Geophysics, University of Western Ontario, London, Ontario, Canada.

HENDREY Mercury Vapour Concentration Meter

Tune F 3472

Measures concentration of mercury vapour present in air. Essential where quantities of mercury are regularly used or where danger exists of leakage of mercury vapour from apparatus.

Two sensitivities are available at the touch of a switch, giving either full-scale meter reading at a concentration of 770 microgrammes per cubic metre of air or full-scale meter reading at a concentration of 200 microgrammes. Terminations provided at rear for operation of a recorder to give continuous readings of concentration present.

Recision Instruments

The POLARMATIC 62 Automatic Spectropolarimeter

NOW O.R.D + C.D

We are pleased to announce that a Circular Dichroism attachment has been designed by the National Physical Laboratory and will shortly be available for this outstanding spectropolarimeter. Like the Polarmatic itself, this new device will once again open up new thresholds in biological research.

A great deal of engineering development has enabled us to offer this attachment to both new and present users of the O.R.D. instrument. For full details write to Dept. N.

We now have capacity for aluminising certain types of mirrors, at short notice.

No More Coal

THE White Paper on fuel policy on which the Ministry of Power has been brooding for the best part of a year has finally appeared, and the delay is to a large extent justified by the quality of the document (see page 628). The ministry has done its best to explain the steps which have led to its new policy as well as the principles on which it will try to hold the ring between the four competitors in the fuel market-coal, oil, natural gas and nuclear power. The ministry has also done a good deal to make an honest woman of the coal industry, which is something to be pleased about. It does not follow, of course, that the ministry will be able to forget about fuel policy for the next few years. The new document is not all that persuasive, and there are bound in any case to be continuing rows about the rate at which the coal industry can be allowed to decline. But at least it is now possible to know with quite exceptional clarity where the British Government stands on fuel policy.

For practical purposes, the new policy runs for the next five years or so. Because of the unavoidable delay between a decision to build a new pipeline or a new power station and the actual appearance of this machinery in service, it is, however, inevitable that the policy now laid down will have an important influence on the pattern of energy consumption in Britain in the middle seventies. The most striking decision is to attempt deliberately to exploit North Sea gas as quickly as possible. The calculation is that by 1975 natural gas will contribute the equivalent of 50 million tons of coal a year to the fuel economy, or 15 per cent of all the energy then consumed. By that time, nuclear power will generate the equivalent of 35 million tons of coal a year. The contributions of oil to the fuel economy will grow, but less quickly than in the past, and the Government has once more shrunk from an honest appraisal of the tax on fuel oil. But in circumstances like these, it is plain that something must decline. The ministry calculates that coal will contribute 120 million tons a year to the fuel economy in 1975-a third of all the energy consumed and two-thirds of the amount of coal produced in Britain in 1966. The ministry makes no secret of the fact that the use made of coal in 1970 is in part determined by the need not to allow the industry to decline more rapidly than is socially acceptable.

Curiously enough, the White Paper is least explicit on its most important decision—to make the fullest use of natural gas. To be sure, the ministry does explain that it has tried to balance its wish to win the greatest economic value from natural gas, which argues for slow exploitation where gas is relatively cheapest, and its wish to obtain the greatest benefit for the economy as a whole, which argues for rapid exploit-On the whole, the Government has plumped for the second course, which is understandable enough, particularly at a time of chronic economic crisis. The trouble is that the scale of investment in natural gas will not bring much price advantage in the decade ahead to those who actually pay for the privilege of burning gas. Without more details than are in the White Paper, there is at least a case for thinking that a middle course on gas would have been preferable. Possibly the ministry will be more forthcoming after it has struck a bargain with the oil companies about the price for natural gas. It may even be that the scale of exploitation is in part at least determined by the hope that oil companies will be more willing to settle for cheap gas if they can look forward to a rapid return on their investments.

The new policy on fuel says nothing new about the future of nuclear power. For practical purposes, there will be something like 10,000 megawatts of nuclear generating capacity at work in 1975, and most of this will have been begun two years from now. If it had not been for the decision to support coal at an artificially high level in the years immediately ahead, or if the British economy as a whole had grown more quickly, there might have had to be an acceleration of this programme. As things are, the interesting question is to know what should happen after 1975. The White Paper has a telling calculation of the natural rate of return on the extra capital involved in building nuclear power stations instead of power stations which burn coal. According to the price of coal, the rate of return from advanced gas cooled reactors is calculated at somewhere between 13 per cent and 33 per cent a year even when the electricity industry pays a royalty on the power stations to pay for past and future development. It would be hard to think of other fields in which the Government could secure such a splendid return on the investment of public funds. A boom in nuclear power in the late seventies is almost unavoidable.

The future of coal is necessarily the most controversial part of the new policy, if only because of the social and even political implications of the rapid decline now openly recognized. In the next five years the industry will lose 35,000 men a year, or 10 per cent of its strength each year. Mr Richard Marsh, the Minister of Power, is certain to be handled roughly by those

who would postpone this inevitable economic process, which is why it is a pity that he has not elected to be hung for a sheep and not just a lamb. It is also unfortunate that he has not included in his new statement some echo of the declaration in the House of Commons last July that in the seventies the competing fuel industries will have to find their own level by price competition in the open market.

But what should be the Government's policy on coal? This is where the ministry may have been too much distracted by the enthusiasm with which it has recently been converted to the doctrine of discounted cash flows as a means of comparing the value of alternative investments. The plain truth is that the market for coal in the 1980s will consist simply of two kinds of customers—the steel works which use coal as a chemical reducing agent and those electricity power stations which, for geographical reasons or simply because they happen to exist, can economically make use of the fuel. There may also, of course, be private persons who continue to burn coal in their houses more out of nostalgia for what will then be the past than as a means of keeping warm. In other words, with luck, Lord Robens' successor in the mid seventies may have to conjure with a natural demand for coal of between 50 and 75 million tons a year. In these circumstances the courageous policy is not so much to fix an acceptable rate of decline for the years immediately ahead as to plan deliberately for what should be a continuing reduction of the scale of the coal industry in the next two decades.

The question is important not merely because coal employs 370,000 miners but also because problems of industrial obsolescence will be increasingly frequent in the years ahead. It is also plain that the concentra-

The Future for Coal

: -

"This is a very complex subject," said Mr Richard Marsh, Minister of Power, warming to the task of presenting his Fuel Policy White Paper on November 14. Complex it may be, but this has not deterred the mining industry, and its supporters, from protesting very loudly about the rapid run-down of the mining industry. Mr Marsh was wise enough not to ignore their fears, but he did say that the manpower figures quoted for 1980—and inspired by the Coal Board—had "no validity whatsoever". "It's impossible to produce serious figures this far ahead." On the contrary, the coal mining industry would remain one of the biggest industries in Britain, producing 120 million tons in 1975, just over a third of Britain's total energy requirement. The claim that the ministry was "slashing the coal industry" could not be sustained in the light of the White Paper. Mr Marsh admitted that the figures would probably be wrong-"Every estimate of coal burning since the War has been too high"-but they were indications of the way things were going, and they could readily be adjusted if necessary.

What the White Paper does is to re-work the estimates made in a previous white paper in 1965. Since then, the emergence of nuclear power as a cheaper source of electricity than coal, and the discovery of

tion of the coal industry in particular parts of Britain means that social problems are not thinly spread about the country but, rather, concentrated painfully. How then to deal with them? The Government has accompanied its new policy for fuel with a number of schemes for softening the blows that will fall in mining communities in the years ahead. There are to be pensions for miners over 55 thrown out of work by the closing down of collieries, and other financial devices operated through the National Coal Board. should go some way to sweetening the bitter pill the miners will have to swallow, but they will of necessity only comfort the older part of the mining population. Indirectly, however, the industry as a whole will benefit from the way in which the Government is arranging that the industry's need of capital investment in the years ahead shall be provided almost entirely from public funds and not out of the industry's own revenue.

By themselves, however, these measures will only scratch the surface of the social problem of a rapidly declining coal industry. The other half of the Government's policy is to offer further incentives for industries to establish themselves in mining areas. But the Government should pay still more attention to the need for a vigorous retraining programme for people thrown out of work by technical change in industry. Given the scale on which the Ministry of Power now hopes to win economic benefit by a shift of emphasis in the fuel industries, it would not be unreasonable if several tens of millions of pounds a year were spent on retraining programmes for miners. For retraining is in its way an investment, just as is the building of new pipelines or new power stations. By comparison, increased doles are merely a palliative, necessary though they may occasionally be.

natural gas in the North Sea, have overturned the assumptions which it was then possible to make. Despite this, and an appendix to the White Paper which argues the case for nuclear power in terms which might almost convince Lord Robens, no increase is being made in the second nuclear power programme—it will still be 8,000 MW by 1975. By then, natural gas will represent 50 million tons of coal equivalent, and oil will be the major source of power, providing 145 million tons of coal equivalent.

Until 1970, Mr Marsh said, the gas and electricity industries had been persuaded to burn an extra 6 million tons of coal a year. The extra cost of this, £45 million, would be met by the Government and not the consumer. Foreign coal will continue to be banned, and oil will continue to be taxed. To alleviate hardship in the industry, the Government is proposing new legislation—the Coal Industry Bill—which will increase the amount the Government contributes towards the costs of redundancy or redeployment. Men between the ages of 55 and 65 who lose their jobs will get a high proportion of their previous wage for three years, or until they are 65. After this they will get their mineworker's pension immediately. There are also to be steps to encourage new industry to areas where pits

will be closed. The Board of Trade is establishing "super-development areas" within existing development areas. The attractions for industry will be even greater—a Board of Trade factory rent-free for five years, for example. Building grants and loans at moderate rates of interest will also be available. This will be costing a total of £100 million in the period up to 1971.

What emerges from all this? First, the coal industry will continue to contract, although the special arrangements will slow the process down in the difficult years up till 1970. Natural gas will go ahead fast, and oil will continue to expand, whatever obstacles are put in its way. Nuclear power will do no more than hold its own, at least until 1970. After that, Mr Marsh may be able to get back to the cheap fuel policy he set his heart on when he first became minister.

Nuclear Confusion

THERE is increasing impatience in industry, and in the Atomic Energy Authority, over the Government's reluctance to announce new plans for the organization of nuclear power in Britain. For the past six months it has been clear that some sort of reorganization is inevitable, but it is still doubtful what form it will take. Part of the responsibility for the delay must be laid at the door of the Select Committee on Science and Technology, which will publish on November 22 its report on the nuclear power industry. The Government is using the report as an excuse, if not for inaction, at least for declining to comment.

Reformers divide into two schools. One, led by the Atomic Energy Authority, favours the setting up of a central design authority, which would do research and design new stations. Individual parts of power stations would be put out to tender, but the formal structure of the consortia would be broken down. Overseas the AEA would tender for contracts, and would be responsible for the export work now done by the British Nuclear Export Executive. Only one consortium, Atomic Power Constructions Ltd, favours this solution.

The other two consortia, and the Central Electricity Generating Board, favour an arrangement which retains at least an element of commercial competition. (The AEA sometimes argues that competition from the USA is going to be more than enough to keep nuclear power in Britain on its toes.) It is generally accepted that the number of consortia would be reduced to two, possibly by a merger between Atomic Power Constructions and Nuclear Design and Construction. The two ministries involved, the Ministry of Technology and the Ministry of Power, agree that discussions have been going on between them, but decline to say what, if anything, has been decided. The Minister of Power, Mr Richard Marsh, did agree with the select committee that the question of the single design authority was crucial. "It is one of the biggest arguments involved in this particular issue."

But this was as long ago as June. Since then, little has been done to clarify the position. It is unlikely, though, that this silence can be taken as evidence of a division of opinion between the two ministries. Reports that the Government is preparing legislation to compel the formation of one central design authority are also heavily discounted in Whitehall. No mention

was made of such legislation in the Queen's Speech, and it would be very hard to find room for it in the parliamentary calendar. But if the idea of a single design authority has found favour, it is hard to see how it could be imposed except by legislation. The only alternative would be to force the consortia into line by an edict from the Central Electricity Generating Board, which buys the stations. If the buying policies of the CEGB were manipulated, then there is no doubt that a single design authority could emerge. The CEGB need only say that in future it would buy stations only from the AEA, and the consortia would soon be forced to knuckle under. Unfortunately for supporters of the idea, the CEGB has not always seen eye to eye with the AEA, and does not approve of the idea of a monopoly design authority. Thus if the Ministry of Technology is really wedded to the idea of a single design authority—and there is some evidence that it is not-it may have to force the idea through the CEGB.

Barriers to Collaboration

EXPORT efforts by British firms are often hindered by tariff barriers. One possible answer is to collaborate with foreign firms and either set up partly owned subsidiaries in the countries concerned or let the foreign companies make the product under licence. Although this sounds simple, Mr C. de Hoghton, author of a report called *Cross-Channel Collaboration* published by Political and Economic Planning (PEP), points out that there are many pitfalls because of different licensing laws, language barriers, the difficulty of finding the right company and the lack of comprehensive advice. Provided the company's outlook is realistic, however, it should not find collaboration with a European firm intrinsically more difficult than collaboration with a firm at home.

Mr de Hoghton points out that there is a profusion of sources of advice and assistance, but these sources are not used because firms are unaware of their existence. In some cases they offer only partial advice and help and they are distrusted, or the companies fail to recognize the need, in certain circumstances, for outside assistance. He recommends that an Institute of Industrial Licensing should be set up as a competently staffed clearing-house to assist firms in the profitable exploitation of their know-how abroad. A pilot scheme, limited to Western Europe, might be run by the British National Export Council.

Among the other recommendations Mr de Hoghton makes are that it should be standard drill for companies to comb through their product lines and their research and development to identify items which could be licensed abroad or exploited by other appropriate means in foreign countries. Both Government and private bodies should give greater publicity to the advantages of collaboration, and especially of collaboration with European firms. Consultants should concern themselves more actively with the whole range of issues raised by collaboration. Trade associations should consider what additional help they could give members who want to collaborate and should always become members of international European associations where they exist, seeking to be admitted as observers to those European associations limited to the EEC.

Few Bouquets for BEA

The committee of inquiry set up in July to examine the civil air transport industry in Britain was sent on its way last week by a report sharply critical of civil aviation in Britain. The report came from the Select Committee on the Nationalized Industries, which spent the last session of Parliament examining British European Airways. Judged by the opinion some people have of BEA, the report was comparatively mild, but there were distinct undertones of criticism. "Whether or not BEA have been slow to change, Your Committee are satisfied that they are changing now . . . It would be churlish indeed if Your Committee's only reaction to new developments were to ask why they were not introduced before. . . . They congratulate BEA on introducing the new methods, and accept them as indications that BEA's management is not at present static or lacking in ideas."

But BEA was not alone in being criticized. In particular, the committee commented on the division of function by which the Ministry of Technology is responsible for sponsoring new aircraft, while the Board of Trade administers civil aviation. As a result, the report says, the formal channels provide for BEA to have contact only with the Board of Trade, while the manufacturers have contact only with the Ministry of Technology. This tortuous link makes it harder for BEA to be heard when decisions are being made at the Ministry of Technology, particularly when the ministry is arguing the specification of the European airbus, which BEA will be expected to buy.

On the other hand, BEA should not have too much say in the design of sircraft. "Tailor-made" aircraft, like the Trident, were difficult to sell abroad—although the Viscount, another BEA aircraft, had been very successful. "Hawker-Siddeley, who agreed to change the specification of the Trident to suit BEA, had regretted it. This part of the report has an important bearing on BEA's current campaign to get approval for the building of the BAC 2-11. BAC first put the idea forward in February 1967, and immediately BEA put in an application for sanction to buy it. At the same time, the airbus negotiations were in progress with France and Germany. If BEA was forced to operate the Trident 3B, another possibility, it would need government compensation (a poor comment on an aircraft designed specifically for BEA's own needs), and if it was obliged to operate with VC 10s, it would need "cnormous" compensation. There the matter stands. BEA is still hopeful of getting the BAC 2-11, and the Government is still committed to the airbus, although Lufthansa, the West German national airline, seems to be having doubts.

The committee was rather more cheerful about BEA's financial record. In the five years from 1963-4, BEA will have reached its target set in 1963, and the committee welcomes this. As for licensing, the committee believes that the Air Transport Licensing Board, set up to grant licences to independent airlines, has become no more than a body from which to make appeals to the Board of Trade. The airlines themselves, the committee says, should be allowed to set their own fares, subject, if necessary, to a reference to the Prices and Incomes Board. Without its licensing or farefixing function, the ATLB would become only a consumers' council. The committee did not think that a

sufficient justification for its continued existence; it should be wound up.

Ceramic Mirror at Siding Spring

A £240,000 contract has been placed with Owens-Illinois of Toledo, Ohio, for the mirror blank for the 150 inch Anglo-Australian telescope which is to be constructed at Siding Spring Mountain in New South Wales. The order was placed by the Science Research Council, acting on joint Anglo-Australian behalf, and follows a decision taken at the first meeting of the Joint Policy Committee in August. The fifteen ton blank, to be delivered in about twelve months time, will be made of a glass ceramic material called 'Cervit'.

'Cervit' materials are produced from glasses of a special composition which are melted and formed in a manner similar to that used for conventional glasses. After these special glasses have been produced in the desired shape, they are subjected to a high temperature heat treatment during which the glass is gradually converted into a micro-crystalline ceramic material through the growth of crystals: the final product is homogeneous. By controlling nucleation and crystal growth, it is possible to produce very small and precisely controlled crystal sizes. Certain selected elements such as aluminium and lithium are incorporated into the crystal lattice, thus enabling the properties of the crystallized glass to be altered so that the expansion coefficient is reduced to very near zero and so that the change in expansion coefficient with temperature remains small over a wide temperature range. The telescopic mirror blank has adequate transparency for examination of defects within the blank and also has excellent polishing qualities. Furthermore, this mirror blank material has a higher thermal conductivity than fused silica and is more dense. The material is also considered stiffer than fused silica and should therefore display less sag across large edgesupported sections than the same shape made of fused

type is that it can be made in a mould in one piece.

Construction of the 150 inch telescope will take about six years. The capital and recurrent cost of the telescope, which is intended for the equal use of UK and Australian astronomers, will be shared equally by the two governments.

silica. The main advantage, however, of a blank of this

New Electrical Giant

MR ARNOLD WEINSTOCK has just managed to hang on to his reputation as one of Britain's more successful businessmen. Mr Weinstock is managing director of the General Electric Company, which last week took over Associated Electrical Industries after a brisk battle. But Mr Weinstock was twice forced to raise his offer, and AEI was able to put up an unexpectedly vigorous defence. After it was all over, things became very chummy, and Mr. Weinstock asked three AEI directors to join the board of the new company. Only Lord Beeching, called in by AEI as a sort of managerial deus ex machina, was left without work. But he is a deputy chairman of Imperial Chemical Industries, which should be enough to keep him happy until something better comes along.

It is tempting to see the takeover as a coming together of opposites—GEC sleek but technically suspect.

AEI engineers par excellence, clumsily managed. Neither company, of course, would accept more than one of these generalizations. The new company will be among the giants of the international electricity industry, although there are several in Europe larger. The Dutch Philips group, for example, is more than half as large again as GEC/AEI in terms of turnover. In the United States, there are five larger companies, headed by General Electric (USA)—no relation to GEC—with a staggering turnover of £7,239 million last year, against £445 million from GEC/AEI. In Britain, only the joint English Electric/Elliott Automation group comes anywhere near the new group—its turnover last year was £334 million.

Mr Weinstock; still cheerful.

There are good reasons for hoping that the size of the new group will bring dividends. Certainly, shareholders will be hoping so, for after the confident predictions of both sides during the battle anything less than complete success is going to feel like failure. Both companies are untidy conglomerates, spreading their activities over a wide range, although GEC opted out of the heavy end of the business several years ago. One of the problems will be deciding what to do with AEI's enormous cable interests, which make up 25 per cent of the company. In other fields the merging of the two companies will be more like a normal process of rationalization, at which Mr Weinstock has shown himself adept. Telecommunications, for example, is ripe for brisk reorganization, and it looks as if AEI's investment in rather dated Strowger electro-mechanical exchanges-which the GPO still needs-will fit in nicely with GEC's work on smaller electronic ex-In transistors and semiconductors GEC changes. has a minority interest in Associated Semiconductor Manufacturers (with Mullard) and AEI runs a joint company with Thorn. Apart from this, the companies have substantial interests in radar, automation and process control, transformers and switchgear and domestic appliances.

As befits companies in such advanced fields, both run extensive research activities (see *Nature*, 216, 8; 1967). These will no doubt feel the effects of rationalization too, but this week Mr Weinstock had nothing to say. The electronics and telecommunications interests may well offer the best chance of saving money by integrating research, but it is doubtful whether anything has been decided yet.

Small Change on Degrees

from our Oxford Correspondent

Last week, Congregation at Oxford resolved, by a narrow margin of votes, to change the university's somewhat anomalous mode of classifying BAs. At nearly all the other universities of Britain, degrees are divided into three classes, the best and worst 10 per cent of students receiving firsts and thirds, and the intermediate 80 per cent being subdivided into upper and lower divisions. At Oxford, four classes have been awarded. Last year, the proportion of firsts was the same as in other universities, at 10 per cent. But there were fewer seconds (60 per cent) and far more thirds (28 per cent). Fourths are rarely awarded, and Congregation voted unanimously to abolish the class.

So what distinguishes the Oxford system is the large size of the third class and the lack of subdivision of the second. The proposers of the resolution before Congregation claimed that some students who received thirds at Oxford, and thereby are financially penalized in certain professions, would have received lower second class degrees elsewhere. This may possibly be true, though account should be taken that few undergraduates drop out of Oxford, while at some universities large numbers of students leave who would otherwise go on to swell the numbers of the third class. But if it is true that an Oxford third could have been a London lower second, the remedy is simple: award more seconds.

The argument for the division of the second class is that those awarded a second vary in ability from the borderline firsts to those who narrowly managed to avoid thirds; that, in fact, the class designates everyone except the very best and the very worst, and is meaningless as a classification. But the nature of the normal curve is such that it is far more difficult to judge fairly who is just above the average than to distinguish the very best and very worst students from the rest. There is also the question of postgraduate studies. Whether or not a student can stay on for a postgraduate course depends on the availability of grants: if he has a first there is no problem; if he has a second, then the matter will rest on his tutor's recommendation and that of his head of department. So the really important classification is not a formal one. Those few employers, notably the Civil Service Commissioners, who draw a distinction between good and bad seconds, can always be informed of the nature of a candidate's degree by his tutor.

Nevertheless, by 101 votes to 99, with a number of abstentions, Congregation has decided to change the degree classes—a narrow vote on a decision that will alter little; still, Oxford may have cause to regret it. Flexibility, by which is meant indeterminacy, is adduced in defence of Oxford's various institutions quite as often as "democracy", and with as little justification in most cases. But in the degree arrangements, perhaps flexibility worked.

Planning Families

1968 has been designated Human Rights Year by the United Nations, and the International Planned Parenthood Federation (IPPF) has responded enthusiastically to the call. The federation, fortified by the belief that knowledge of contraception is a fundamental human right, has just announced that the estimated expenditure for 1968 is over £2 million, double the 1967 figure. Voluntary associations for family planning in fifty countries make up the federation, with support from the governments of Britain, Sweden, Denmark, Holland, Norway and the USA, as well as charitable During the coming year effort will be institutions. concentrated in areas where there are no government supported programmes, particularly in Latin America, where population is growing faster than in Asia, despite high abortion rates. If the present growth rate continues, the population of India will have trebled in under 50 years, while that of Brazil will have quad-

It is hoped that sufficient funds will be raised to make individual grants to twenty-one Latin American countries, the largest going to Brazil, to equip clinics and train personnel, as well as to provide education programmes which are essential if the schemes are to be successful. Mobile clinics are planned for various parts of the world, particularly in Kenya and West Africa, and—the nicest touch of all—a riverboat will take family planning to communities round the waterways of East Pakistan. The Indian offer of money for men willing to be sterilized has sometimes been described as bribery, but last week Lady Rama Rau, president of IPPF, said the benefit—only about £1—is given to make up for the lack of hospital facilities.

As well as work on a practical level, the IPPF finances a Basic Sciences Committee to discuss and evaluate the laboratory research which is in progress on the various aspects of human reproduction and its prevention. Professor A. S. Parkes, formerly professor of physiology of reproduction at Cambridge University, has been appointed chairman of this committee. Two new groups of specialists have been established to cover educational matters. One will investigate family planning in the teaching of doctors and nurses, and the other will advise on the best methods of bringing knowledge of family planning to organizations and individuals in different parts of the world.

Human Development

A CENTRE for Advanced Study in the Developmental Sciences is being established near Oxford, for the promotion of interdisciplinary communication and growth of knowledge in the behavioural sciences. Dr A. Ambrose, formerly at the Tavistock Institute and now director of the centre, has been largely responsible for the project from its beginnings, and has donated Minster Lovell Mill which will house the centre By providing a specialized library and facilities for study groups, individual study and short courses, the centre will allow specialists from all parts of the world and from all disciplines to meet and exchange ideas on human development and the factors which are likely to cause deviation from normal behaviour. No basic research will be carried out at Minster Lovell, but fellowships will be awarded for

research to be carried out wherever suitable material is available. Proceedings of study group discussions will be published to bring the cross-fertilization of ideas to a wider audience.

Considerable building and alteration work is being done at the mill to provide accommodation for $3\overline{0}$ people, as well as a library and conference rooms, but meanwhile the centre is beginning its scientific activities in accommodation provided by the Ciba Foundation in London. The first study group is being held this week on the functions of stimulation in early postnatal development, and is being attended by 15 people from all parts of the world. The centre, which will be controlled by a specially set up Developmental Sciences Trust, will be managed by an executive council consisting of Professor Brian Foss, Dr Ronald Mackeith, Mr John Marsh, Dr Christopher Ounsted and Dr Gordon Wolstenholme. The scientific advisory panel, constituted on an international basis, includes Dr J. Bowlby, Professor M. Abercrombie, Professor R. Hinde, Dr E. Leach, Professor J. Tanner and Professor N. Tinbergen. An appeal will be launched in the spring to raise £0.5 million which will be required to run the centre for five years.

Stopping Supertankers

As tankers get larger and larger, so does the problem of stopping them. Dr Hatsuko Tani, of the Tokyo University of Mercantile Marine, discussed the problem in a paper presented to the Institute of Navigation on November 15. Dr Tani discussed three ways of avoiding obstacles; putting the helm hard over, reversing the engines, or doing both at once. Until twenty years ago, he said, the distance needed for a ship to come to a stop in a straight line with the engines full astern was comparable with the forward distance travelled if the helm were put hard over. The distance in the first case is called the head reach, and in the second is called the turning advance. For a modern tanker weighing 100,000 tons, on the other hand, the head reach is between ten and fifteen times the length of the ship, while the turning advance is only five to seven times the length. This slightly surprising result comes about because the mass of the ship—and hence the inertial forces—increases with the cube of the length, while the total resistance of the hull underwater increases with the square of the length.

From the captain's point of view, it is vital to know how soon the ship can be stopped, both for everyday activities like picking up pilots, anchoring and berthing, or for emergencies like avoiding collisions or going aground. Dr Tani described theoretical studies which enable calculations of the head reach to be made. To make the problem even easier, he plotted the figures on a diagram. Comparison of the theoretical results with experience on two large supertankers and a medium size tanker (the Esso Suez) had shown that the calculations produced the right answer to a very fair degree of accuracy.

But this takes no account of the third possibility—that of reversing the engines and putting the helm hard across at the same time. The distance taken to stop in this case Dr Tani calls the stopping advance, and it depends on speed, as well as the other sailing characteristics of the ship. Turning advance, on the other hand, is virtually constant within the normal speed

range, and depends only on the rudder angle and not on the speed. At high speeds, therefore, the turning advance is smaller than the stopping advance; as speeds falls, the two become identical, and at low speed stopping advance is the shorter of the two. (This takes no account of the tendency of the ship to behave irrationally when the rudder is hard over and the propellers reversing. Occasionally under these conditions ships make sharp turns, often to starboard, either because of the unbalancing effect of the right-handed screw propeller, or, in Dr Tani's opinion, because the course stability of the ship becomes extremely poor.)

What conclusions can the captain draw from these unexpectedly complicated considerations? At high speed, a full rudder turn is probably the best course, without reversing the engines. At lower speed, reversing the engines and putting the helm hard over may be best. If the object to be avoided is approaching—as, for example, in a collision situation—the important criterion is to reduce speed in as short a time as possible; in this case, although the ship may be travelling above the critical speed, a crash-back procedure with engines in reverse is recommended.

Saturn Aloft

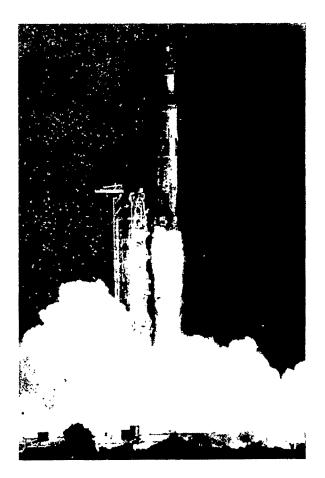

from a Correspondent

Last week's first Saturn V flight (called Apollo 4) may have helped NASA to catch up on the lagging timetable for landing two Americans on the Moon by 1970. By combining in one flight the first operational tests of several important components, time has been saved and many of the tactical obstacles to the first manned flight in the Apollo capsule cleared away. That flight is now fixed for autumn 1968, employing the less powerful Saturn I as booster for a low Earth orbit to check the capsule under "live" conditions. At least three further steps of graduated difficulty must follow before the lunar landing attempt.

There is no doubt of the technological achievement of the first Saturn V flight, however misplaced or outdated may now seem the goal of a manned Moon landing by 1970. The organization and co-ordination by themselves compare with an important military exercise—with far less margin for improvization. That the launching took place to the minute—0700 hours local time, October 8—marks the planning efficiency and the soundness of the new Moonport Complex 39 at its first launching.

The chief engineering tasks to be met were these. The unflown first stage (F1), presumed the biggest booster ever to take off, used conventional fuel, but to concentrate a thrust building up to 8.5 million pounds within 150 seconds depended on the fine adjustment and balance of the supply of 28,000 pounds-per-second of propellant for simultaneous burning in five matched The second stage, delivering one million pounds, had never flown before and used tricky liquid hydrogen as propellant in its five clustered $(\hat{J}-2)$ engines. To ensure smooth transfer of power between stages, eight solid fuel rockets used for stage separation also had to "settle" the super-cooled liquids in the bottom of their tanks to ensure instant feed under high vacuum and weightlessness. The third stage centred on a single liquid hydrogen J-2 engine, with fourteen other rockets for ancillary purposes. The critical and pre-

viously untried test for this stage was to restart the main engine after two Earth orbits to push the vehicle out to a distance (9,300 nautical miles) whence it could start a simulated lunar return and re-entry to prove the Apollo capsule's heat shield. This involved accelerating it downward by means of further rocket burns and high precision onboard control only partly prompted from the ground to ensure correct attitude, angle and so on, to narrow margins for the high speed collision with the atmosphere. A glancing blow, 7·13° (to local horizontal), on the heat protected blunt forward end of the spacecraft was called for, and achieved.

More Action on Aldabra

CONVINCED that Aldabra Atoll should be preserved entire without the air staging post which the Ministry of Defence wants, the Royal Society has made a further approach to the Secretary of State for Defence. Since its last approach in May, the society has reappraised the case in the light of the results of the preliminary ecological survey of the atoll and of recent modifications to the defence proposals. These proposals would limit any development, if and when a decision is taken, to the eastern end of the south island, instead of involving all the islands of the atoll as originally planned.

The Royal Society has repeated that any development on Aldabra will upset the integral ecosystem, which is the great scientific interest of this, the last remaining ecosystem of its kind in the Indian Ocean. Confining the air staging post to one part of one island will not save the ecosystem. It would not be possible

to put effective barriers between parts of the atoll, and in any case the eastern area of the south island is the most interesting part of Aldabra. Once development begins, the destruction of the ecosystem, which has been occurring very slowly ever since domestic animals and weeds were introduced by the settlers who arrived in 1888, will be accelerated, and the ecosystem as it is now—largely unaffected by man—will eventually be destroyed. In its new approach the Royal Society has stressed the great value of Aldabra as an integrated island ecosystem the study of which would give information valuable not only to biological science but also for the understanding of other ecosystems, including those of economic and social importance.

New Post

Following the discovery of natural gas, the Gas Council announced, in its annual report earlier this year, a reorientation of its research policy into two sectors, one to cover current problems and the other to investigate the full and economic use of natural gas. The council is now advertising for a distinguished scientist to direct all research activities, which means taking charge of the five research establishments and an annual expenditure of at least £2.5 million. The post is a new one and remuneration is a matter for discussion, but corresponding research posts in the National Coal Board and the Central Electricity Generating Board command salaries in the £7,000 to £9,500 range.

Safe Vaccine

A NEW method for preparing canine distemperhepatitis vaccine in established cell lines of canine kidney tissue has been developed by Dr L. Brown, director of the biological research division of Norden Laboratories Inc., Lincoln, Nebraska. Dr Brown described the method at a conference for the Division of Biologics Standards at the National Institute of Health, Bethesda, on November 6–8. The vaccine—containing two attenuated live vaccines and called 'Enduracell D-H', has been used to vaccinate approximately one million dogs since it was first introduced in 1963.

There are several advantages in using an established cell line for vaccine production. A cell line of this nature contains only one kind of cell and every cell is genetically related: each cell therefore has the same biochemical characters, the same growth rate, the same virus susceptibility and, when infected with a virus, will respond in the same way. As a result, vaccine production is very regular; it contains a uniform virus concentration and has consistent antigenic potency. It is important to use cells for vaccine production from the same species in which the vaccine will be used. This ensures that the virus maintains its maximum ability to invade cells of a given species, resulting in maximum immunity. It also reduces the danger of foreign protein reactions.

The DK line is produced from a master seed stock and every serial of vaccine is produced at the same passage level. This development of uniformly potent and safe vaccine is to be extended to the production of rabies vaccine for dogs, cats and cattle, and Dr Brown anticipates that it will soon be possible to prepare all vaccines in established cell lines.

Parliament in Britain

Oceanography

DR J. BRAY, Joint Parliamentary Secretary, Ministry of Technology, said that research was proceeding with the hope of increasing the range of optical detection in turbid water, and the National Research Development Corporation, in conjunction with the Ministry of Defence, had patented and was exploiting a non-optical imaging system for underwater viewing. The corporation had for some months been studying with a group of industrialists the requirements of a technologically based diving activity, and this group was now engaged in generating the necessary development work to produce a wide range of aids and equipment for submarine use. In common with the governments of other member countries of the United Nations, the Government was cooperating in a comprehensive survey of activities in marine science and technology, with a view to formulating proposals for an expanded programme of international cooperation in oceanography. (Written answer, November 7.)

Biological Warfare

THE Minister of Defence for Equipment, Mr R. Mason, said that the Government's policy was to publish as much as possible of the results of microbiological research at the Porton Laboratory. Last year forty papers by the staff of the Microbiological Reresearch at the Porton Laboratory. search Establishment were published and members of the staff gave lectures and attended national and international symposia. An annual report, in the form of abstracts of all original work published, was issued to about 300 libraries at universities, research institutions and industrial organizations, and copies were available on request. From December 1, 1967, all suitable unclassified departmental reports would be released to the National Lending Library for Science and Technology. Much of the work was helping the medical research centres. (Oral answer, November 8.) Weather

MR. M. Rees, Under-Secretary of State for Defence for the Royal Air Force, stated that over the next four years the British contribution to the World Weather Watch was expected to amount to some £2·5-£3 million, or about 7 per cent of the total cost. Britain had offered to act as a Regional Meteorological Centre and a Regional Telecommunications Hub, to continue to develop its research effort, to improve surface and upper air observations and to provide free training for overseas meteorologists. In addition, he said, Britain would make substantial amounts of equipment available for use for developing countries and would make an additional annual contribution of £30,000 to the World Meteorological Organization. (Written answer, November 8.)

Student Grants

MRS SHIRLEY WILLIAMS, for the Department of Education and Science, said that grants to students in the current academic year would cost an estimated £129 million. £9 million of this was for postgraduate awards and the remainder for first degree courses. Mr Patrick Gordon Walker said the raising of the school leaving age to 16 in 1971–2 would cost £44 million in the first year. It was too soon to tell, he said in answer to another question, whether the £0.5 million set aside for aid to overseas students would prove adequate. (Written answer, November 9.)

NEWS AND VIEWS

What Future for Biogenesis?

Those who work on the origin of life must necessarily make bricks without very much straw, which goes a long way to explain why this field of study is so often regarded with deep suspicion. Speculation is bound to be rife, and it has also frequently been wild. Some attempts to account for the origin of life on the Earth, however ingenious, have shared much with imaginative literature and little with theoretical inference of the kind which can be confronted with observational evidence of some kind or another. But if biogenesis has been plagued by too much speculation, exobiology, as it has been called, has suffered more grievously. It is still hard, for example, to be reconciled to the use of good public money on the solemn search for extraterrestrial life which rejoiced—the correct word—in the name of project OZMA. To be sure, there is no good reason to shrink from accepting as a working hypothesis that there are living things elsewhere than on the Earth. It would be a great surprise if one planet were unique in this respect. But, even if it is now necessary to suppose that there are living things elsewhere, it is surely unreasonably innocent—and even unimaginative -to think that a search of the radio sky would yield more than anecdotal information. In this and a host of other ways, biogenecists and exobiologists have earned themselves a bad name. This is a misfortune, for the hard core of these studies now deserves close and careful attention.

There has, in any case, always been a hard core, and it goes back at least to Lyell and his contemporaries. More recently, Haldane occupied a distinguished place. And now, in the past decade or so, a great many developments have conspired to stiffen speculation and to make it more absorbing. One way and another, problems of the origin of life have come to occupy a central position. The surge of interest in geophysics in the past decade has stimulated a great deal of enterprising work. A better understanding of the relationships between the various chemical components of the present atmosphere has, for example, made speculation about the reducing atmosphere of the early Pre-Cambrian a much more certain process. The comparative study of the planets, now easier than it used to be, has worked in the same direction. Superficially unrelated processes such as continental drift have drawn attention to the need to know more about the processes of mountain building and to the feasibility of doing so. It should not be too long before people are

Tests for Pregnancy

THE Royal Postgraduate Medical School at Hammersmith Hospital was founded as a part of the University of London to provide a centre for specialist teaching and medical study. It receives approximately £340,000 a year in grants and benefactions as well as a grant from the university.

able to define stratigraphical horizons in the Pro-Cambrian with at least some of the certainty with which this can be done in the Pleistocene.

Molecular biology has been a great spur. It is true that the apparent simplicity and sureness of the genetic code raise awkward questions—how can such a simple and sure means of replication have come into being more or less in one fell swoop? And, if it did not, what else happened? But these are speculative questions. There is more profit in less ambitious directions. The understanding of photosynthesis has raised all kinds of questions about the origin of life. There is the possibility that photosynthesis may discriminate against the naturally occurring and stable isotope carbon-13 in such a sure way as to provide an indication that ancient samples of petroleum, for example. have been formed in ways like these. But photosynthesis has also emphasized the relative stability of the porphyrin structure. It is no wonder that people go about with excitement when they have found traces of porphyrins in ancient sediments, much as if they had found the fossil of some new kind of dinosaur.

In practice, recent developments of technique in biochemistry have given the hunt for traces of primeval chemicals a great stimulus, which brings obvious benefits but which creates problems as well. Some of the benefits are at once valuable in themselves and provoking of other questions—the ways in which amino-acids and other materials are being found in Pre-Cambrian materials (see Nature, 216, 561; 1967) are important illustrations of this principle. The nature of some of the problems is illustrated by the article by Professors Eugene McCarthy and Melvin Calvin on page 642, and proves how sensitively some of the problems must be dealt with. The argument is that quite complicated chemicals can be built up by inorganic processes—if matters were organized differently, the whole question of biogenesis would be enormously complicated. It follows, however, that there must be serious problems in distinguishing between fossil chemicals derived from living things and those which have been constructed by other means. At the same time, it is also clear that establishing criteria to decide issues like these will be an absorbing task. A great many of the other problems of biogenesis have this important quality. This is why these studies deserve more attention, more support and more respect than they have usually attracted.

Part of the research in the Department of Obstetrics and Gynaecology at the Medical School is a project concerned with foetal heart monitoring in early pregnancy by means of ultrasonics. Using the Doptone foetal pulse detector, the presence of the foetal heart can be detected before foetal movements are felt by

the patient and before the conventional foetal stethoscope can be of value. The guiding principle used is the doppler effect. A beam of low frequency ultrasound is directed into the uterus of the patient. Some of this is reflected at every density gradient which the beam traverses. Stationary structures reflect ultrasonic beams at a frequency different from that reflected by moving structures and this difference in frequency is used to demonstrate movement in vessels or in the foetal heart. The alteration in pitch is recorded on a tape and can be heard on a loudspeaker. Preliminary studies have shown that the foetal heart can be heard as early as the tenth week of pregnancy.

Women often forget the stage of pregnancy which they have reached; a simple technique has therefore been developed in the department to estimate accurately foetal maturity. This is a cytological test, based on the fact that, as the foetus matures, fat cells become more numerous and desquamate. A catheter is introduced into the uterus and 10 millilitres of amniotic fluid is removed. Samples of the liquor are placed on slides and stained with nile blue sulphate—cells containing lipid stain orange-brown. One can then count the number of cells containing lipid and compare the results with previously obtained values. For example, between 34 and 38 weeks of pregnancy, 1-10 per cent of cells contain lipid. After term, more than 50 per cent of cells stain orange and it is then safe to induce birth when necessary.

Bacterial Walls

BACTERIOLOGISTS have come a long way since Leeuwenhoek first observed and described bacteria under the microscope. During the last ten years, particular attention has been focused on the structure and function of the bacterial cell wall. This subject formed the basis of this year's Royal Society Leeuwenhoek Lecture, entitled "Teichoic Acids and the Molecular Structure of Bacterial Walls" and given by Professor J. Baddiley on November 9.

Professor Baddiley began by outlining the importance of the bacterial cell wall: it is important in conferring shape on the organism; it is interesting because of its strength and permeability to metabolites; it is the site of many serologically active substances and, furthermore, certain antibiotics such as penicillin and vacitracin effect their antibacterial activity by interfering with cell wall synthesis. Cell walls are also interesting in their own right, as they contribute up to 20 per cent of the dry weight of the micro-

Isolated walls can be prepared by several methods, including mechanical disruption with tiny glass beads, after which the material is subjected to filtration, washing, differential centrifugation and further washing. The chemical structure of the wall depends on the kind of micro-organism. Thus in Gram-negative bacteria, it is a complex of lipid, protein and carbohydrate; in Gram-positive bacteria, the structure is simpler, and it is on this latter group that Professor Baddiley concentrated. He pointed out that the cell walls of these Gram-positive bacteria contain two principal components—mucopeptides and teichoic acids. Mucopeptides give the cell wall its structural rigidity: they consist, essentially, of a polysaccharide chain containing acetylglucosamine and cetylmuramic

acid residues, to which are attached short peptide side chains. They constitute approximately 50 per cent of the cell wall.

Teichoic acids constitute 30 or 40 per cent of the dry They are phosphate polymers containing either ribitol or glycerol residues joined through phosphodiester linkages. In most cases, sugars are attached to the polyol units and D-alanine residues are in labile ester linkage with hydroxyl groups. The length of the teichoic acid chain is not accurately known but is probably in the region of 15 to 20 units and varies according to the size of the organism. Variations on this basic structure have been found in a number of bacteria, for example in Streptococcus griseus, Bacillus subtilis and Staphylococcus lactis, and an atypical teichoic acid has also been found in the Pneumococcus capsule. Professor Baddiley described how, using the enzyme lysozyme, a membrane associated teichoic acid has been demonstrated in addition to the wall teichoic acid. This suggests that teichoic acids could be concerned with regulating the transport of metabolites and ions, as the densely charged environment created in, or beneath, a cell wall by their presence must surely influence the passage of electrolytes.

The overall biosynthesis of teichoic acids from nucleotide precursors is largely understood, but the process of attachment of alanine and the exact sequence in building up the polymers are not yet clear. It has, moreover, been suggested that a lipid is involved as a carrier in the transfer of glycerol phosphate or ribitol phosphate from the nucleotide precursor to the polymer: this lipid is probably C55-polyisoprene.

Hummingbirds and Plant Speciation

from a Correspondent

In California many species of hummingbird are migratory, moving from lowland desert in winter and spring to the mountainous regions in summer. Grant and Grant observed (Aliso, 6, 51; 1966; and 103 and 107; 1967) that hummingbirds are the pollinators of many Californian plant species whose floral parts may be adapted to receive the bird's bill. The Grants now suggest (Evolution, 21, 457; 1967) there is a relationship between the migration of the hummingbirds and speciation of plants in areas occupied by the birds. One step in speciation may be a change in floral structure, another may be a change in the time of flowering; both changes facilitate contact with the hummingbirds to the advantage of both flower and bird.

The Grants have found that in the lowlands, the flowering period of plants pollinated by hummingbirds falls in the winter and spring, and this coincides with the occupation of these regions by the hummingbirds before migration. Here the hummingbirds are widely dispersed, the different species showing habitat preferences and territorial activity. The hummingbird flowers tend to be allopatric, that is, one species predominated in the areas studied. By contrast, in the mountainous regions the hummingbird flowers are summer flowering, and here they are sympatric-up to six species occurring together within the area studied. During the summer in the mountainous regions hummingbirds of different species are collected together. There seems to be a definite pattern of distribution of hummingbirds and the character of the species they pollinate. The suggestion is that the higher the density of hummingbirds the greater the selection pressure they exert to produce suitably adapted plants and hence new races and species. This is the situation in the mountainous regions which are sites of high selection pressure on each of the species present, and is revealed by the sympatric nature of the hummingbird flower population. The allopatric population in lowland areas indicates a less intense selection pressure. A similar correlation of hummingbird dispersion and plant speciation has been found in Arizona, and is expected to occur in other areas over which the hummingbirds migrate.

Underground Shrimps

AMPHIPOD crustaceans are among the largest and least studied groups of North American freshwater invertebrates. It is therefore useful that a complete reappraisal of the systematics, speciation and distribution of the subterranean amphipod genus *Stygonectes* has been reported by John R. Holsinger in Bulletin 259 of the United States National Museum.

With 29 species, Stygonectes is the largest of the nine genera of Gammaridae. Mature adults range from 4·50 mm-19·50 mm; they lack eyes and pigments and inhabit subterranean areas such as caves and solution channels in limestone regions, and interstitial habitats where there is underlying non-cavernous rock. The genus has been divided into six species groups which are geographically distributed in the eastern United States, the south-central United States and central Texas.

The origin of Stygonectes is difficult to work out because of the complete lack of a fossil record and because of the absence of marine forms which can be regarded as related to an ancestral stock. Nevertheless, Holsinger has postulated a theory based on a series of freshwater invasions by ancestral marine stygonectic stock beginning early in the Cenozoic or even in the Ancestral stock was probably Upper Cretaceous. already inhabiting shallow coastal waters at this time and later passed through a transitional stage in brackish waters during periods of marine embayment. As the sea waters fluctuated, ancestral forms slowly migrated into freshwater areas lying adjacent to the old coastline. Finally, as the sea water permanently receded, they became tolerant of changing salinity and, as they established themselves in fresh water, moved slowly inland to occupy a whole series of newly created niches. Subsequent inland dispersal occurred through interstitial habitats developed in flood plains along principal rivers.

Three lines of evolution are indicated within the genus on the basis of morphology, geographic distribution and, to some extent, ecology. Patterns of insular speciation in the emarginatus and spinatus groups of Stygonectes in the central Appalachians, and in the flagellatus and hadenoecus groups of the Edwards Plateau, can be explained in terms of geographic isolation. Thus in the Appalachians, species in limestone-floored valleys were isolated from each other by high ridges of shales, sandstones and conglomerates. Similarly, ranges in the Edwards Plateau were isolated by barriers in the form of extensive faults and stratigraphic changes. Species with the widest range are found in the tenuis group and disperse freely through ground waters which are situated close to the surface.

Some instances have been reported in Maryland of breakdown of ecological isolating mechanisms between two otherwise phenotypically and genotypically distinct species.

Dr Holsinger also considers recommendations for future study on the evolutionary biology of the genus. These include experiments to determine toleration to varying concentrations of salt water and improving methods to clearly delineate patterns of geographic variation.

Protein Protons

from our Molecular Biology Correspondent

THE past year has seen the burgeoning of proton magnetic resonance as a means of looking at the behaviour of particular functional groups in biological polymers. Some new examples in the current literature demonstrate again the scope and potential of the method.

Following on earlier work, Bradbury and Wilairat (Biochem. Biophys. Res. Commun., 29, 84; 1967) have examined the characteristic resonances of certain protons-specifically the C-2 ring protons-of the histidine residues in several proteins. It was shown previously that in ribonuclease, signals corresponding to different histidines could be distinguished. It is now shown that in hen's egg lysozyme the solitary histidine is clearly observable and that, in native insulin, cytochrome c and myoglobin peaks likewise show up in the expected region. On the other hand, in trypsin, chymotrypsin and their zymogens no histidine signals are detected until the protein is denatured. The simplest explanation, and the one offered by the authors, is that in the latter group of proteins the histidine rings are immobilized by interactions with their environment, whereas in the others they are presumably essentially free to rotate. Since protonation of the imidazole ring leads to a downfield shift, it is possible to follow its ionization curve, and Bradbury and Wilairat give the pK of the histidine residue of lysozyme as 6.3 in D_2O (corresponding to about 5.8 in H_2O).

The same experiment (with happily the same result) has been described by Jardetzky's group (Meadow et al., Proc. US Nat. Acad. Sci., 58, 1307; 1967). In a human lysozyme these workers find the quite different, and anomalous, pK of 7.6. The addition to hen's egg lysozyme of a specific inhibitor leads to no detectable shift in the histidine resonance. In pancreatic ribonuclease, however, interesting effects are observed. In the first place, the 100 Mc instrument used by Meadows et al. makes possible the resolution of signals from all four histidine residues. Their hydrogen ion titration curves have thus been individually measured, and pKvalues of 5.6, 5.9, 6.1 and 6.6 ensue. Further, it is known that two histidines, his-12 and his-119, flank the active site, and their chemical modification annihilates the activity of the enzyme. Progressive addition of the competitive inhibitor, cytidine monophosphate, leads to quite large shifts in the signals from first one and then another of the histidines, and ultimately the remainder also show appreciable effects. There is no doubt, however, that two of the residues are most strongly affected, and it seems highly probable that these are near the active centre.

A staphylococcal nuclease, which requires calcium for activity and has also four histidine residues, has been similarly studied. Here, however, addition of inhibitor leads to no significant shifts, and it therefore seems likely that in this enzyme histidines are not directly involved in the active site. The pK values of the four residues have been measured, and one—the least readily protonated—shows evidence of interaction with calcium ions.

A minute study of the NMR spectrum of lysozyme has been described by Sternlicht and Wilson (Biochemistry, 6, 2881; 1967). This represents a beginning to the formidable task of allocating all the observed resonances: from the crystallographic co-ordinates it has been possible to calculate interactions (for example, ring-current shifts of methyl protons close to aromatic rings), which has made possible a near-certain identification of several signals from side chains and backbone. The changes occurring on thermal unfolding have been described.

A review, including much new work, of results obtained with the celebrated new 220 Mc Varian instrument also requires mention (Ferguson and Phillips, Science, 157, 257; 1967). This shows yet again, and in spectacular fashion, the resolution of the four histidine residues of ribonuclease, and the changes observed when ribonuclease and lysozyme are denatured. It will be noted that all the other work which has been mentioned was performed with 60 or 100 Mc instruments. Wider applications in enzymology may be expected.

More about Chain Initiation

from our Cell Biology Correspondent

GIVEN the great variety of proteins in ribosomes, it has always been a puzzle why ribosomes consist of two subunits; there seems to be no a priori reason why a single particle could not fulfil all the ribosomal functions. To explain the existence of subunits it has been suggested that during protein synthesis there is a cycle involving their separation and also that there is some division of the ribosomal functions between them. Several recent experiments, most of which are reported in the last two numbers of *Proc. US Nat. Acad. Sci.*, confirm both these suggestions.

Nomura and his collaborators (Proc. US Nat. Acad. Sci., 58, 946 and 1487; 1967), Eisenstadt and Brawerman (ibid., 1560) and Hille et al. (ibid., 1652) have all reported on the specific role of the 30S ribosomal subunit in the initiation of polypeptide chain synthesis in E. coli. The following general scheme emerges from their data—which are in gratifying agreement—and from previous results. First, initiation factors, which stimulate formyl methionyl tRNAF binding to ribosomes programmed with the initiating codons AUG or GUG, bind to the 30S subunit. Then the 30S subunit binds mRNA and F-met tRNAF to form an initiation complex, an obligatory intermediate of initiation. It is now generally agreed (Ohta, Sarkar and Thach, ibid., 1638) that this binding of F-met tRNAr is GTP dependent although GTP may not be split at the binding stage but during the formation of the first peptide band. And according to Economou and Nakamoto (ibid., 1033) the methionyl residue is formulated before it binds to a ribosome, but this is still a disputed point. Once the initiation complex has formed a 50S subunit, it couples with it to produce a 70S ribosome attached to mRNA and with the chain initiator in place. Only when this has happened can other amino-acyl tRNA bind and the

first peptide bond be formed. The requirement of the 50S subunit for peptide bond formation is in agreement with Munro's results (J. Mol. Biol., 26, 147; 1967) which suggest that the enzyme necessary for this, peptidyl transferase, resides in the 50S subunit. Once polypeptide synthesis has been initiated Eisenstadt and Brawerman envisage the initiation factors leaving the 70S ribosome and binding to another free 30S subunit. This would explain why initiation factors must be added to get initiation in vitro with 70S ribosomes while the 30S subunit forms an initiation complex without added factors and can then couple with a 50S subunit. It also explains why initiation factors are not found free in the soluble extracts of E. coli.

At chain termination and release of the completed protein the 70S ribosome dissociates into 30S and 50S subunits and if the 30S subunit picks up more initiation factor the cycle can be repeated. Mangiarotti and Schlessinger's (1966) discovery that the ribosomal population of E. coli consists of free 30S and 50S subunits and polysomes without a pool of free and stable 70S ribosomes clearly provides evidence for this. Moreover, Schlessinger et al. (ibid., 1782) now report that free 30S and 50S ribosomal subunits from E. coli do not spontaneously associate to form 70S ribosomes but will associate in the presence of mRNA, tRNA, K+ and Mg++ ions. The 70S ribosomes seem to be stabilized by peptidyl tRNA, for when peptide chain release is effected with puromycin they dissociate into 30S and 50S subunits.

So far, of course, all the experimental evidence for this scheme comes from work with *E. coli*, but it is unlikely that the process of protein synthesis should differ fundamentally in eucells. Indeed, there have been several reports—the latest by Sells and Takahashi (*Biochim. Biophys. Acta*, 134, 69; 1967)—that in nucleated cells mRNA associates with the small ribosomal subunit in the nucleus and then migrates to the cytoplasm; it would be no surprise if these complexes prove to be initiation complexes involving newly synthesized mRNA and small ribosomal subunits.

The Genetic Code in vivo

by our Molecular Genetics Correspondent

THE detailed relationship between amino-acids and their trinucleotide codons has been established for Escherichia coli over the past six years. Of the sixtyfour codons, three are nonsense (UAG, UAA, and UGA) and the remainder code for the twenty natural aminoacids. The evidence for constructing this dictionary of codons and amino-acids has come essentially from two different types of biochemical experiments, both carried out in the test-tube. The first of these is the triplet binding technique in which a single trinucleotide is used to select and bind the correct transfer-RNA molecule carrying its amino-acid to the ribosome. This experimental approach, developed in Nirenberg's laboratory, is limited because of the rather small The second experimental set-up, effects observed. developed in Khorana's laboratory, utilized defined messenger RNAs with simple repeating sequences to direct the synthesis of polypeptides whose sequence was then determined. This, then, has provided us with the genetic code of E. coli in vitro.

It is far from easy to establish that this is exactly

the way in which the code is translated in vivo. There are two rather different tests which can be applied at present to see whether the in vitro code agrees with the in vivo code. First, base analogue-induced mutations are a single change of one base for another which should lead to the change of one amino-acid for another in a predictable fashion. Thus, a mutation which changes methionine (AUG) to valine (GUG) produces a change consistent with the in vitro code. Many such examples are known.

A more powerful approach utilizes a different type of mutation—the acridine mutation. In this case, as shown by Crick, Brenner and their colleagues in 1961, a whole segment of the gene is misread because an extra base has been inserted into the nucleotide sequence of the DNA, giving rise to a similar extra base in the messenger RNA. This extra base throws the translation of the messenger RNA out of its normal reading frame as the triplet codons are read, one at a time. However, if another base is deleted in a second mutation farther down the gene, the original phase of reading will be restored with a piece of phase-shifted sequence in between the two mutations. the original gene reads . . . ,AAA,BBB,CCC,DDD,EEE, ..., insertion of an extra base Y will give the following misreading: . . . ,AAY,ABB,BCC,CDD,DEE,E . . , . . . Finally, a further deletion of a C will give ..., AAY, ABB, BCC, DDD, EEE, ..., so that we finish up in the original phase with a bit of sequence altered in between. Two tests of this have now been made in E. coli; in the first case Streisinger and his colleagues studied such double acridine mutants of the phage T4 lysozyme (Proc. US Nat. Acad. Sci., 56, 500 and 1692; 1966), and recently Yanofsky and his group have determined the sequences of similar mutants in the tryptophane synthetase A protein of E. coli (Proc. US Nat. Acad. Sci., 58, 1499; 1967). Below are illustrated some of the mutants these groups obtained:

```
lysozyme (wild):
... thr. lys. ser. pro. ser. leu. asN. ala ...
... ACU.AAA.AGU.CCA.UCA.CUU.AAU.GCC ...
... ACU.AAA.GUC.CAU.CAC.UUA.AUG.GCC ...
lysozyme (mutant):
... thr.lys.val.his.his.leu.met.ala ...
tryp. synthetase (wild):
. thr. tyr. leu. leu. ser. arg. ala. gly ...
... ACC.UAU.UUG.CUG.UCA.CGA.GCG.GGU ...
... ACC.UUU.UGC.UGU.CAC.GAG.CAG.GGU ...
tryp. synthetase (mutant):
```

The collective results show that all the acridine mutants so far reported confirm the codons assigned to amino-acids by the *in vitro* system. This covers about one-third of all the triplets.

thr.phe.cys.cys.his.glu.glN.gly . . .

Furthermore, these data not only confirm codon assignments but show us which codons are in fact used in vivo. Since T4 phage has a higher AT base composition in its DNA than $E.\ coli$ (the (A+T)/(G+C) ratio is about 0.66 and 0.50 respectively), we might not expect T4 and $E.\ coli$ to use the same codons. Although the samples of codons used are still small, it is nevertheless striking that T4 appears to prefer to use triplets ending in A or U instead of equivalent (standing for the same amino-acid) triplets ending in a G or C. Just the reverse appears true of $E.\ coli$.

Phage RNA Replication

from our Cell Biology Correspondent

When I last wrote on the replication of single stranded RNA bacteriophage (see Nature, 214, 1287; 1967), Spiegelman's group had finally convinced themselves that this replication involves the synthesis of complementary minus strands and thus accepted the principle that in general replication of single stranded nucleic acid molecules requires synthesis of a complementary strand. Weissmann's group, however, had challenged the conventional view that replication of RNA phage genomes involves a replicative form (parental plus and minus strands hydrogen bonded in a duplex) which serves as a template for synthesis of progeny strands and so gives rise to a replicative intermediate (the duplex with nascent single stranded progeny molecules attached). They suggested that the minus strand (not the hydrogen bonded duplex) is the template for progeny plus strands and that the replicative form and intermediates are artefacts derived from the actual replicative complex during isolation.

The only way to test this idea is to isolate pure minus strands and determine their template function. Weissmann et al. (Proc. US Nat. Acad. Sci., 58, 766; 1967) and Inglewski and Frankin (ibid., 1019) have achieved the first step, the isolation of Q and R17 minus strands. Both groups used essentially the same method which involves annealing denatured replicative form with fragmented plus strands and then separating the minus strands from the hybrid of minus strand and plus strand fragments. The pure minus strands are, as expected, not infective and now the crucial experiments are doubtless being done.

Meanwhile Kelly and Sinsheimer (J. Mol. Biol., 29, 229 and 237; 1967) have reported a new technique for isolating replicative intermediate and have used it to test whether nascent progeny strands displace parental plus strands from the duplex (semi-conservative replication) or whether the original parental plus strand remains in a duplex with a minus strand while the progeny strand is displaced (conservative replication). Their experiment is based on the assumption that the replicative intermediate is a precursor of progeny strands and contains a double stranded core and this ignores any changes in structure that might occur during isolation which, of course, is just what worries Weissmann. Kelly and Sinsheimer find that, when the nascent strand is labelled with a short pulse of radioactivity, only about half of the label is displaced from the replicative intermediate. It is surprising that, when the parental plus strand of the duplex is labelled before replication, then again about half the label is displaced. As there is evidence that no duplexes are conserved throughout a complete infective cycle this result indicates that there is an about equal probability that any particular replication cycle will be either semiconservative or conservative and that all molecules are involved in both mechanisms at some time during the infective cycle.

The sugar phosphate chain of all nucleic acids has chemical polarity because of its 5' 3' phosphodiester links, and the usual direction of synthesis of nucleic acids is from 5' to 3'. Bishop, Pace and Spiegelman (*Proc. US Nat. Acad. Sci.*, 58, 1790; 1967), however, report evidence that although the synthesis of the minus strand during Q β RNA replication begins at the 5'

terminus, as usual, the polarity of synthesis of the progeny plus strands in the replicative intermediate is reversed and proceeds from 3' terminus to 5' terminus. This so far unique example of 3' to 5' synthesis predicts that the first part of progeny plus strands present in early replicative intermediate have a base composition similar to the 3' end of the completed plus strand and that progeny plus strands can be initiated before the

minus strand template has been completed. Apparently, both these predictions have been verified by experiment but, characteristically, the details are to be published separately. As translation proceeds in a 5' to 3' direction, the 3' to 5' synthesis of progeny plus strands must surely mean that translation of these strands cannot begin until their transcription has been completed.

Mathematics in 1984

Dr Brian Thwaites, the new president of the Institute of Mathematics, believes that Britain is failing to exploit the powers of the computer in mathematics. The following is an extract from his presidential address, given on November 16.

My subject is comprehensive in its own way because it embraces indiscriminately the whole of mathematics. It arises from a belief that the practice of mathematics is destined to be entirely changed by the computer. Our present pencil-and-paper method will, in the historical perspective, be likened to the industrial methods of the Stone Age.

I would therefore like to outline some of the reasons which have led me to this certainty. I have made no particular effort to pick out the most significant examples or to mention the most advanced techniques.

First, the ultimate objective of mathematical investigations into physical deterministic systems is the production of numbers. Soon, computers will be able to produce whatever numbers are required far more effectively than our conventional theoretical methods. Second, the analytical apparatus in our mathematical tool-kit is, in fact, extremely primitive; the computer offers us a power of technique which will transcend all our present capabilities.

The power of future machines therefore faces the present-day applied mathematician with the brutal question "What am I after and how do I achieve it?" I fear that, in this country, most of us would answer this in too cautious and conservative a fashion. In the other two major world mathematical communities, in the USA and Russia, there is evidence of a much more vigorous approach. Let me quote just two papers from Russia. These refer to the equations of three-dimensional supersonic and hypersonic flow, equations to which an enormous theoretical effort has been devoted, with Russian mathematicians having made particularly notable contributions. Now come two papers by Babenko et al. (Nat. Aero. Space Admin. Tech. Transl. 380) and by Belotserkovskii et al. (Basic Developments in Fluid Dynamics, edit. by Holt, M.; Academic Press, New York) which seem to me to mark a decisive turning point in the theoretical study of this particular area of science. They set out, from the start, to exploit the resources of the computer and, in doing so, tackle problems far outside the limits of analysis.

As an aside, one may wonder whether such papers are the first fruits at the research level of the great emphasis which has been placed since the War on computers in mathematical education in Russian schools, technical colleges and universities. The report of the Ditchley Mathematical Conference and a recent report soon to be published by the Schools Council (Thwaites, B., Mathematical Education in Russian Schools (to be published)) highlight this situation, whose significance our own Department of Education and Science seems to have quite failed to grasp if one may judge from the recent report on

computer education by an interdepartmental working group (HMSO, 1967).

In regard, therefore, to the famous canonical equations of mathematical physics, one can say that it is no longer fanciful to imagine the facility of calling up standard programmes for the solution of, say, the complete Navier-Stokes equations stored as a kind of sub-routine in a large computer, so that the only actual programming that needs to be done by the user is to input the boundary condition of his problem, the degree of accuracy he requires in the solution, and the type of output. Certainly the construction of such a sub-routine is an immense task, but once completed it is there for good. It is a little odd that the British scientific community seems deliberately to shun the undertaking of this type of task which would bring such tremendous benefits.

I am, of course, aware of the argument that research into fundamental physical mechanisms, the discovery of effects which are strongly coupled, and the interpretation of natural observations all require more than merely the production of numbers. But these activities of the research mathematician are akin in character to those of the pure mathematician and I hope to indicate later how the computer is already active as an indispensable laboratory assistant to the pure mathematician. Moreover, the applied mathematician needs to go further than the pure; his theories are not sufficient unto themselves: whatever their sophistication, they must still be tested against observation. And, since the essence of scientific observation is quantitative measurement, numbers are, in the end, inescapable. They are, in my submission, becoming inescapable throughout.

Input and Output

So far, I have been talking in pretty trad terms and I must now move on to my second line of argument, namely that our mathematical tool-kit is soon to be enlarged beyond recognition. Whatever you may think of the potentialities I have been describing, those in the non-numerical field are far more startling. Our pencil and paper, therefore, give way to the teleprinter and the cathode-ray tube.

The teleprinter is no longer primarily the means for the input of a programme or its output; it is the medium of conversation between the mathematician and his mathematics. Mathematics is written into the machine which will ask questions back if it does not quite follow the argument; manipulations are made and calculations requested; chunks of mathematics are stored away to be retrieved later or fitted into a larger scheme. All this requires a language of conversation. At present, there are almost as many different languages as there are specialists working in this field, though they show strong affinities to each other. Far too little effort is being put in this country into this crucially important field of conversational languages; indeed, as far as I have been able to discover, the only reasonably comprehensive and readily available programme in the United Kingdom is at the Department of Machine Intelligence at Edinburgh University.

[Dr Thwaites then went on to describe the application of the cathode-ray tube, allied to lightpens, and the use of computers in pattern recognition. He also discussed the role of computers in abstract mathematics, in the finding or proving of theorems. One day, he said, computers would be programmed to emulate the feats of the finest mathematicians. He then gave examples of the use of the computer in the manipulation of real functions of a single real variable. But what conclusions should be drawn from these demonstrations of the power of the

computer ?]

All that I have described should have the most profound influence on the content of mathematical courses, in schools and universities, and on teachers' attitudes to mathematics. As to the content, there should first be much greater emphasis on discrete mathematics than there has been in the past. In the lower stages of education, where in any case attention has always been focused on the integers and on various practical uses of the integers, the notion of finite, rather than infinite, sets, and the idea of closed binary operations defined on such sets, should now be made explicit—as indeed is typical of some of the projects for the reform of main-school mathematics. In the higher stages—in the sixth form and above -the stress which is laid on continuous and on differentiable functions should be relieved by much greater emphasis on the discrete analogues of the kind I exempli-In particular, the notorious "methods" fied earlier. courses should be drastically overhauled in an attempt to anticipate the kinds of methods which today's students may be using in ten years' time.

Equally, mathematics must no longer be presented to the student—at whatever level—as a system involving proofs, demonstrations and other chunks of argument which are prescribed by some immutable and probably divine law. It seems to me essential that our students should be consciously reared on the algorithmic approach, duly spiced with heuristics; essential, too, that they should be taught explicitly that the methods to be employed in any piece of mathematics, and the chances of success, must depend on the means available, on the acceptable cost in time for man and machine, and on the use to which the result is to be put. In particular, the idea of graphs—that is, of the possible states of a system, and of the operative connexions between the states—is one which should now permeate all the teaching of mathematics.

Next, I want to suggest that the character of an intellectual discipline in its higher reaches, and the attitude which its practitioners adopt towards it, depend strongly on the manner in which the subject is presented during the period of formal education. Or, to put it differently but quite starkly, if schoolchildren are using techniques with which university dons (for example) have yet to catch up, then there is trouble ahead.

This is, in fact, now the situation. Young children at the very beginning of their conscious lives are doing mathematics by computer—with their own keyboards, CRTs and lightpens; in constant dialogue with the computer which is responding to their own efforts in an individual personalized manner which far exceeds what they could experience from any teacher facing a class of thirty-five children; and, as a final twist, the computer is also talking to them through the earphones.

This is not a vision of the future; it is with us now, being developed with immense vigour by people such as Suppes at Stanford University and exploited with equal vigour by firms such as I.B.M. This is what the practice of mathematics means to a coming generation of children; and this is how they will expect to practise mathematics when they are older.

Having been a schoolmaster myself for a number of years, and with a deep nostalgia for the classroom atmosphere, I can well understand the misgivings that many teachers will have in connexion with such developments. Prophecy turns to certainty, however, when in the glass ball one sees at least one of the two major world communities actively evolving such teaching methods. It is another measure of England's coming technological decline that, as far as I know, no group or institution in this country is even planning such activity.

A Short View

Earlier this evening, I took a long view of the development of mathematics, in recognition that there are those who will deny the changes that I have tried to exemplify. Now I am bound to take a shorter view; indeed to confess that I myself have erred on the side of conservatism in choosing 1984 as characteristic of these changes.

For I have not been indulging in any flights of imagination; I have kept my feet most firmly on the ground by describing what is actually now being done. I am not really looking forward seventeen years at all—if I were, I should have much more startling and controversial things to say. After all, east your minds back seventeen years to 1950: the "state of the art" now in 1967 far transcends what would then have been realistically predicted for 1967. There are solid reasons for supposing that a shot now at a realistic prediction for 1984 would fall equally short of the target.

I am therefore concerned not so much with the potentialities for 1984, but with the absence of potentialities in 1967. The lethargy which seems to be inhibiting British mathematics from realizing the changes inherent in computers has many manifestations.

First there is the evidence of the literature. Even if one goes no further than to say that the use of computers is one of the strongest growing points in mathematics. the British effort is already dangerously small in comparison with that of Russia and the United States.

Then there are the consequences of the future experimental nature of mathematics. We now need a great variety of sophisticated laboratory equipment, each piece precisely designed for the type of problem to be tackled. Thus university departments should be clamouring insistently for specific and detailed requirements for software, programming languages, and multi-access facilities. As it is, I suspect that the Computer Board is showing more imagination than mathematics departments. refer, for an example, to my own university, London; the very generous provision recently announced includes no facilities of any substance which are, in a significant mathematical sense, forward looking. That this may be inevitable in the present economic climate is beside the point; it remains that in their submission last year the university's mathematicians—and I am one of them—did not show the imagination and the professionalism which should be expected of them.

Finally, in looking at the more general national need of education in computer usage, I refer again to the recent Government report on an interdepartmental working group on computer education. This is a derisory piece of work. The members of the working party may shelter behind their terms of reference; if so, the terms of reference are derisory. In either event, it must be a matter of deep national concern if this document in any way reflects Government thinking on the applications of computers either to mathematics in particular or to the technological society in general. It is of high importance that within the next two or three years, this problem of computer education be examined by another body with knowledge and foresight.

Organic Geochemical Studies. 1. Molecular Criteria for Hydrocarbon Genesis

by EUGENE D. McCARTHY MELVIN CALVIN

Laboratory of Chemical Biodynamics and Space Sciences Laboratory, University of California, Berkeley, California In organic geochemical studies, it is important to develop criteria for distinguishing between chemicals produced by inorganic means and those which are the product of living processes. Molecules which consist of isoprene units have been particularly important, and abiogenic construction now seems possible.

THE search for forms of life in the earliest periods of geological time has been carried on not only at the morphological level but also at the molecular level. This has been possible as a result of the increase in biochemical knowledge and with the advent of analytical techniques that make it possible to describe the intimate molecular architecture of individual molecules in fine detail. The fundamental premises upon which this organic geochemical approach rests are that certain molecules, possessing a characteristic structural skeleton, show a reasonable stability to degradation over long periods of geological time, that their structural specificity can be understood in terms of known biosynthetic sequences and that their formation by any non-biological means is of negligible probability. In this article it is proposed critically to re-examine these premises and to establish criteria whereby one can differentiate molecules derived from biological systems from those which originate from non-biological One important reason for establishing such criteria is that they can be used to determine whether life exists, or has existed, on other planets. It may be possible to provide an initial answer to this question in the very near future when the first lunar samples are returned to the Earth for analysis.

Almost all classes of organic compounds which are recognized as the constituents of living organismsnucleic acids, the proteins, the organic pigments, the carbohydrates and the lipids-have been sought in sedimentary deposits of the geological environment. All these fulfil, to a first approximation, the requirements of structural specificity, but only the lipids and, to a lesser extent, the class of organic pigments known as porphyrins, survive from the earliest periods of geological time to be related to their original form today. All organic compounds in the geological environment are unstable with respect to temperature. The rates of thermal degradation processes therefore depend on the nature of the organic compound and upon the geothermal temperatures to which it has been subjected. Because some geothermal temperatures are often quite low and may not have exceeded 30° C (ref. 1), organic compounds may survive for long periods of times in the geological environment. Conway and Libby² measured the rate of a very slow reaction—the dicarboxylation of the amino-acid alanine—under various conditions and with radioactive labelling and low-level counting techniques. At room temperature, the half-life for decarboxylation was found to be about 10° years; at higher temperatures (420-430° K) the half-life was only 100 years. This experiment suggests that at low temperatures, amino-acids derived from the hydrolysis of proteins could be stable over millions of years. In agreement with this prediction, Abelson³ has identified a series of aminoacids, including alanine, in a Trilobite fossil believed to be 450 million years old.

Other classes of organic compounds might be expected to survive these relatively mild thermal conditions of geological environment. The stable tetrapyrrole portion of the porphyrin molecule, for example, has been identified in sediments of Pre-Cambrian age⁴. On the other hand, the

carotenoid groups of organic pigments are easily destroyed at temperatures of about 200° C (ref. 1), which is in keeping with the almost total absence of these compounds in sediments greater than 20,000 years old.

Of all the classes of organic compounds, the lipids have been most widely sought in the geological environment and the occurrence of a series of hydrocarbons, with structures based on the C_5H_3 isoprene unit, has been invoked as evidence for life-forms in Pre-Cambrian times. In particular, two hydrocarbons, phytane, thought to be derived from the phytol side chain of the chlorophyll molecules, and pristane, derived from phytol and also present as such in some marine organisms, have been sought in Pre-Cambrian sediments.

Their architectural skeleton, which has a methyl branch every four carbons, is stable over long periods of time. Hydrocarbons which can be related to the steroids and triterpenoids have also been found in ancient sediments. Examples from this class are cholestane⁵ and gammacerane⁶ whose structures are shown:

The saturated hydrocarbons are more stable than the porphyrins¹ and would be expected to survive in the geological environment through periods of time greater than the presently accepted age of the Earth (4·5 × 10° years, approximately). It is therefore not surprising that isoprenoid hydrocarbons have been consistently found in Pre-Cambrian sediments¹-1¹. Simple calculations of the degradation of hydrocarbons by thermal cracking mechanisms¹² indicate that hydrocarbons should be stable for more than 10²² years, at room temperature, and for 10¹² years at 100° C. The presence of catalysts in the geological environment will presumably accelerate the rates of these processes.

The characteristic architecture of the isoprenoid hydrocarbon molecule has until recently been generally accepted as a marker of biological origin. This is why the idea has arisen that the isoprenoid hydrocarbons might be used to designate the period in geological history when the transition from chemical evolutionary development to biological evolutionary development was made.

The absence of isoprenoid hydrocarbons in the organic extract from a Pre-Cambrian sediment might serve as a criterion for the period of chemical evolutionary development. That such a transition should exist and that evolution should be continuous, not only in the domain of living organisms, was a concept

that Darwin himself had clearly recognized.

The expectation that such a transition might be recognized at the molecular level of evolutionary development has not been realized for several practical reasons. Most important among these is the scarcity of known Pre-Cambrian sediments that might form a chronological sequence from the earliest periods of the Earth's history to the advent of the Cambrian (600 million years). Moreover, only a few of these sediments have been studied from the organic geochemical standpoint. A more fundamental reason why this transition may not have been recognized, however, has now arisen with the development of a nonbiogenic stereospecific polymerization of the isoprene molecule to produce polymers which are identical with the isoprenoid polymers synthesized in the living system. The characteristic structure of the isoprenoid molecule may not be as specific as once was thought. In attempting to recognize this transition in evolutionary history, therefore, it is necessary to establish criteria which will distinguish between those organic compounds—particularly the hydrocarbons—that are derived from abiogenic sources and those that are derived from living systems. Only when this has been achieved can this transition point be recognized with any reliability.

Biosynthesis of the Isoprenoid Structure

The biosynthetic pathway of the isoprenoid hydrocarbons has been fully elucidated (for a general review, see refs. 13 and 14). In the biological system, isopentenyl pyrophosphate plays an important part. This five carbon fragment is the precursor of all the intermediates involved in the isoprenoid pathway.

$$\begin{array}{c} \mathrm{CH_2} \\ \parallel \\ \mathrm{CH_3--C--CH_2--CH_2O--(PP)} \end{array}$$

Polymerization of this five-carbon unit takes place by displacement of the pyrophosphate group to give a 10-carbon fragment, or monoterpenoid compound. The displacement, which involves a head to tail linkage, takes place in a stereospecific manner¹⁵. This biological mechanism is repeated in further polymerization reactions. The head to tail mechanism is, however, replaced by a tail to tail linkage at two places:

(1) The C₁₅ compound farnesyl pyrophosphate reacts with another molecule of farnesyl pyrophosphate to give the hydrocarbon squalene.

(2) In the biosynthetic pathway to the carotenoids, C_{40} terpenoid compounds, an analogous tail to tail linkage is formed between two C_{20} compounds.

The biosynthetic pathway has other stereospecific characteristics. Lindgren 18 has shown that homologous aliphatic $\rm C_{30}-\rm C_{45}$ terpenols occur in extracts of birch wood (Betula verrucosa Erh.). These alcohols have the general formula

$$H--(CH_2--C(CH_3)=CH--CH_2)_n--OH$$

where n is 6,7,8,9. About 60 per cent of their double bonds have the cis configuration. Thus C_{30} terpenoid and C_{40} terpenoid structures containing both the tail to tail linkage and the head to tail linkage have been isolated from living organisms. Higher terpenoid compounds have been isolated from pig liver, which is a rich source of dolichol.

Dolichol has fifteen or sixteen of its eighteen internal isoprene units in the *cis* configuration¹⁷.

$$\begin{array}{c|cccc} CH_3 & CH_3 & CH_3 \\ & | & | & | \\ CH_3-C=CH-CH_2-(CH_2-C-CH-CH_2)_{18} & -CH_2-CH & CH_2-(CH_2OH) \\ \end{array}$$

Isoprenyl alcohols, whose structures have been character ized as undecaisoprenol-1 and dodecaisoprenol-1, and solanesol have been isolated from silk worm facces 18 . Solanesol had been characterized earlier by other workers 19 , who had isolated it from flue-cured tobacco. Its structure was confirmed by Erickson et al. 20 and by Kofler et al. 21 as a 12 -isoprenoid compound. Mevalonic acid, a precursor of isopentenyl pyrophosphate in the biosynthesis of choles terol, is also an intermediate in the biosynthesis of ubiquinone, vitamin K and the tocopherols, all of which contain the isoprenoid side chain 22 .

The biosynthetic pathway to rubber and gutta, which is also a polyisoprenoid and is produced by a small number of tropical species, has been discussed by Bonner²³. Both rubber and gutta are polymeric substances containing iso prene units linked together through 1,4 linkages. Rubber contains from 500 to 5,000 isoprene units, while gutta contains about 100 units. It is of interest that the double bonds of the individual isoprene molecules are in the cis configuration for rubber and in the trans configuration for gutta. No high polymers have been found which contain both the cis and trans geometry.

Non-biogenic Synthesis of the Polyisoprenoid Structure

The biological polymerization mechanism involves a stereospecific 1,4 linkage of the individual isoprene molecules and it is this feature that has been hitherto assumed a unique aspect of the biosynthetic pathway. But recent studies on the non-biological polymerization of small molecules, such as propylene and butadiene, have indicated that these reactions proceed with considerable stereospecificity.

Natta was the first to show that butadiene, isoprene and 1,3 pentadiene are converted to polymers containing 99 per cent of linear 1,4 trans structures by means of a highly stereospecific catalyst Al(Et)₃-VCl₃ (molar ratio 2:1) in heptane²⁴. The presence of even small amounts of impurities impairs the stereo-specificity of the reaction. The infrared spectrum of the polymer resembles that of natural rubber. X-ray diffraction studies show the linearity of the polymers and a periodicity of 4.82 Å along the main axis. The use of TiCl3 produces a stereospecific 1,4 cis linked polymer. The exact mimicking of the stereospecific features of the biosynthetic pathway in the terpenoid series dispels the notion that the head to tail linkage is unique to biological systems. Natta has also shown that not only the 1,4 trans configuration of the biopolymer, gutta, but also the 1,4 cis configuration of the natural rubber can be reproduced by non-biological methods. These findings seriously question the validity of the isoprenoid compounds as "biological markers". Certainly the structure of the isoprenoid hydrocarbons taken in isolation can no longer be considered to be unambiguously derived from a biological precursor. Instead their occurrence in crude oils and sediments must be viewed against the background of the other components present25.

Non-biogenic Polymerization Processes and Chemical Evolution

An empirical approach to the evolutionary development of the first living organisms is to simulate in the laboratory the types of chemical reactions that could have taken place in the primitive atmosphere and given rise to the simple organic molecules that constitute living organisms today.

Such experiments have met with considerable success. By analogy with the atmospheres of other planets, the primitive Earth probably had an essentially reducing atmosphere consisting of hydrogen, methane, ammonia and water. Most of the fundamental building units of living systems, including the amino acids, the sugars, the purines and the pyrimidines, have been synthesized in varying amounts in "primordial atmosphere" experiments where energy, such as ionizing radiation in the form of particulate or gamma radiation, acts on this mixture of gases.

Any chemical evolutionary theory which accounts for the synthesis of the polyisoprenoid compounds in the primitive atmosphere by invoking polymerization reactions of the Natta type, utilizing reduced metal catalysts, must, at the outset, provide a feasible experimental route to the isoprene molecule. No such pathway has been proposed which has been justified on an experimental basis.

Consideration of a well-established commercial process which has been used in industry for many years suggests a possible synthetic route to isoprene in the primordial atmosphere. Isoprene is produced in significant quantities as a side-product in the thermal cracking of a mixture of propane and ethane²⁶. These two hydrocarbons are fed into a pyrolysis furnace in various amounts and undergo thermal cracking at temperatures approaching 1,100° K. In the primitive atmosphere, the starting materials for this pyrolysis reaction, ethane and propane, could be generated from methane in the presence of an external energy source. At 1,000° K these reactions proceed endergonically with a change in free energy amounting to about 17 and 32 kcals/mole, respectively. In a typical feed in addition to ethylene and propylene, sizable quantities of isoprene and butadiene are produced by thermal cracking at 1,100° K (see Table 1).

Table 1
Starting materials: 50 per cent ethane, 50 per cent propane.

	Rel. amount (per cent of product)*					
Ethylene	30					
Propylene	6-8					
Butadiene	2					
Isoprene	0.2					
Renzene	2					

^{*} The remaining 60 per cent is H_2 , CH_4 , and unreacted C_2H_5 .

In a natural environment the shock wave of a sizable meteoritic infall²⁷ would produce the high temperatures and high pressures necessary for this reaction in a pulse of only microseconds to milliseconds duration.

There is no reason to suppose that subsequent polymerization processes in the primitive atmosphere should be confined exclusively to isoprene. Indeed, one would expect that polymerization processes involving isoprene would proceed more slowly than polymerization processes involving the other three molecules. Unlike the molecule of ethylene, the propylene molecule is structurally asymmetric and so it can polymerize in various steric configurations. Under carefully specified conditions, stereospecific polymers may result—the so-called "iso-tactic" and "syndiotactic" polymers. Stereospecific Stereospecific polymerizations of butadiene may also give rise to ordered configurations²⁸. Natta has also shown that a *cis* polybutadiene can be synthesized with a steric purity exceeding the steric purity of the 97 to 98 per cent cis units found in natural rubber.

One may reasonably question the relevance of such polymerization reactions to the kinds of reactions that took place in the primitive atmosphere. All these polymerizations require specific catalysts to produce polymers of a given steric configuration. The likelihood of these particular catalysts being available on the primitive earth is somewhat remote. On the other hand, the overall simplicity of the polymerization reaction, taking place in the presence of metals in their reduced oxidation states

and using only isoprene as a starting material, gives credence to the hypothesis that stereospecific polymerization reactions similar to those developed by Natta might have taken place in the primitive atmosphere, and that the characteristic 1,4 trans head to tail linkage of the polyisoprenoid compounds may not be confined solely to biosynthetic mechanisms.

Even if this hypothesis is accepted, one has to explain why only the polymerization mechanisms giving rise to polyisoprenoid compounds survived to become an integral part of the biological system. There is no obvious reason why the polyisoprenoid compounds should be retained in evolutionary development in preference to the analogous polymers based on propylene or butadiene. Many of the polyisoprenoid compounds belong to the general class of biological components known as the lipids; the lipids themselves form an important part of the membranes of The role of lipids in the transition from living cells. chemical evolution to biological evolution may have been especially significant. Oparin²⁹ has suggested that an essential step in the transition between these two evolutionary stages might be the formation of membranes around droplets of organic substances produced in the primitive atmosphere. It may be that there is some important structural feature, as yet unrecognized and confined only to the polyisoprenoid compounds, that makes these polymers the best structural constituents of cell membranes. As a result, only the polyisoprenoid compounds would have survived the transition into biological evolution. At present this is a purely speculative hypothesis without experimental foundation.

The Fischer-Tropsch reaction has been considered by protagonists of the abiogenic theory for hydrocarbon formation to be a significant process in the formation of petroleum. (The Fischer-Tropsch reaction is a catalytic reaction involving carbon monoxide and hydrogen at temperatures between 200° C and 300° C and at atmospheric or higher pressures.) Friedel and Sharkey30 were the first to demonstrate that a similarity exists between low molecular weight alkane isomers (up to C₈) in crude oil and those characterized in the Fischer-Tropsch reaction product. This hypothesis has recently been extended by Hayatsu and Anders to account for the formation of hydrocarbons in the early solar system³¹. Using a mixture of carbon monoxide and deuterium to eliminate the contamination danger, they provided mass spectrometric evidence for the presence of a series of deuterated isoprenoid hydrocarbons, ranging in carbon number from C₉ to C₁₄. One member of this series, C₁₁D₂₄, had a structure identical to the C11H24 hydrocarbon, 2,6 dimethylnonane, which these workers had identified in the Murray meteorite. Ambiguities can arise in the structural characterization of isoprenoid hydrocarbons where the evidence is based on mass spectrometry alone³². However, if the identification of a homologous series of isoprenoid hydrocarbons is confirmed in the Fischer-Tropsch reaction product this series would be identical with that reported by Göhring, Schenck and Engelhardt in an Italian cretaceous shale³³. In effect this would provide an abiogenic route to the lower molecular weight isoprenoid hydrocarbons that can be vindicated on an experimental basis.

One of the weaknesses of the Fischer–Tropsch theory as a possible inorganic origin of petroleum is that it has not been able to account for the higher molecular weight isoprenoid hydrocarbons (C₁₅–C₂₁), including pristane and phytane, which are found ubiquitously in crude oils and shale extracts as the major components of the "branch-cyclic" hydrocarbon fractions. Furthermore, steranes, triterpanes and hydrocarbons derived from carotenoid precursors have not been demonstrated in the Fischer–Tropsch product, whereas these classes of organic compounds have been identified in both Pre-Cambrian and more recent sediments^{4,5} and in crude oils. The Fischer–Tropsch reaction product therefore only partially resembles

the hydrocarbon constituents of crude oils; it does, however, show a closer resemblance to hydrocarbon extracts from meteorites. As a possible route to the polyisoprenoid hydrocarbons in chemical evolutionary development, this process seems to be subject to the same limitations as in accounting for the isoprenoid distribution in crude oils.

Criteria for Biogenic Origin

The experimental evidence points overwhelmingly to a biogenic origin for almost all the organic extracts of crude oil and shales. However, the origin of the organic material extracted from meteorites^{34–36}, thucholite samples³⁷ and hydrothermal deposits³⁸ is much less clear cut. As the recent polymerization studies of Natta have brought into question the validity of isoprenoid hydrocarbons as "biological markers", it is important to search for criteria which will unambiguously resolve these uncertainties. The same uncertainties about the origin of the organic extracts may very well arise when lunar samples are returned to Earth for analysis.

One of the many approaches adopted in endeavouring to find criteria which will determine whether organic material has an abiogenic or biogenic origin involves the determination of the precise stereochemistry, and particularly the absolute configuration of the optical centres, of the individual constituents of organic extracts.

Optical activity measurements in the past have, in general, been confined to a complex mixture of extracted organic material. Nagy et al. 39 observed optical activity in the organic extract from the Orgueil meteorite, and on the basis of this and other evidence invoked a biological origin for the organic material. Subsequent work on carbonaceous chondrites by Urey⁴⁰ and Nagy⁴¹ provided additional evidence for the presence of optically active material in such sources. Hayatsu42 has consistently criticized the experimental foundation on which this evidence rests. Even if the experimental foundation were verified, however, it is doubtful what the significance of optical activity in a complex mixture would be unless it were possible to relate the origin of the optical activity to a specific component within the mixture, and to correlate this optical rotation, in magnitude and direction, with a known biological compound. Furthermore, the spontaneous formation of optically active substances from an inactive material, without interference from a directing, asymmetric agency, has been demonstrated by experiments. Havinga43 showed that methyl-ethyl-allylanilinium iodide may crystallize spontaneously into either enantiomer under certain experimental conditions. In general, if a nucleus of one type of enantiomeric crystals should begin to form by spontaneous, statistical fluctuations, an autocatalytic crystallization process may set in, because such a nucleus tends to grow by the addition of enantiomeric molecules of similar configuration. observation suggests a mechanism for the formation of the first optically active substance and indicates that optical activity may not be a unique property of the biological system.

In any experimental approach it is necessary to carry out as many measurements as possible of an individual compound to designate an unambiguous structure. We have, however, made no attempt to determine the stereochemistry of the isoprenoid hydrocarbons isolated from crude oils and shales nor, in general, have such determinations been made by other research workers in organic geochemistry. There are very good reasons for this. Until very recently the very specific structural architecture of the "biological markers" was in itself considered adequate evidence for a biological origin. With the isoprenoid hydrocarbons, for example, the characteristic methyl branch at every fourth carbon atom is so specific that it has generally been accepted to be indicative of a biogenic origin. Further, it is very difficult to isolate the individual components in sufficient quantity and purity from the

very complex organic mixtures to obtain a reliable optical measurement. Finally, with the isoprenoid hydrocarbons in particular, the optical rotations are so small that much larger quantities of the compound than normal (20–50 mg). as opposed to the optical measurements carried out by Hills and Whitehead⁴⁴ on milligram amounts, are required. It is impossible to obtain such quantities of individual compounds from most interesting organic geochemical samples and so few optical measurements have been made^{44,45}.

Despite this experimental difficulty it is important to correlate the stereochemistry of the geological samples with that of the biological precursor from which they are thought to be derived. It might be possible to separate diastereoisomeric forms of a particular isoprenoid hydrocarbon using capillary gas chromatography; preliminary attempts to bring about this separation have so far not been successful in our laboratory. Pristane can exist in two forms, and pristane isolated from marine sources is thought to have the mesoconfiguration.

(1) Meso-form

D on C(6), D on C(10)

(2) Mixture of d,l isomers

The separation of very small amounts of pristane into the diastereoisomers by capillary gas-liquid chromatography would provide a major breakthrough in experimental techniques in organic geochemistry. More significantly, it would establish a criterion to distinguish organic compounds derived from abiological sources from those derived from biological sources for, a priori, one would not expect a C₁₉ saturated isoprenoid hydrocarbon, having exclusively the mesoconfiguration, to be produced in an abiogenic synthesis.

Another criterion for biogenic origin stems from the biosynthetic pathway to the polyisoprenoid compounds in the living system. This pathway is dominated by the occurrence of the head to tail linkage in the polymerization of isopentenyl pyrophosphate, but a characteristic tail to tail linkage seems to take place exclusively at C15 to give C₃₀ compounds such as squalene, the precursor of the steranes and triterpanes, and at C20 to give C40 compounds such as lycopene. It may be that the non-branched fourcarbon unit in this tail to tail linkage is the criterion we are searching for to assign a biological origin to compounds isolated from crude oils and sediments. We have made several as yet unsuccessful attempts to identify such a 4-carbon unit in organic geochemical material32. The occurrence of a C21 saturated isoprenoid hydrocarbon 2,6,10,14-tetramethylheptadecane, in a series of sediments suggests that a C40 isoprenoid hydrocarbon such as lycopene, containing a tail to tail linkage, might be a pre-cursor⁴⁶. But it does not demand such a precursor and higher head to tail polyisoprenoids, such as solanesol and dolichol, can be postulated as precursors. The experimental evidence also seems to indicate that the C30 isoprenoid hydrocarbon, squalene, does not play a significant part as precursor to the isoprenoid hydrocarbons.

When isoprene is polymerized abiogenically, one might predict, a priori, that the reaction should not proceed stereospecifically, and that three compounds should be formed—the head to tail linkage (h-t), the tail to tail linkage (t-t) and the head to head linkage (h-h). This is illustrated below:

Isoprene
$$(h-t)$$
 $(h-t)$

When we consider the addition of another molecule of isoprene to produce a C₁₅ compound, and a further molecule to give a C₂₀ compound, then several products should result whose structural skeletons are shown in Fig. 1. These compounds might be expected to be present in hydrocarbon mixtures if they were derived by an abiogenic process which did not proceed stereospecifically. Thus, the presence of such structures in organic extracts might be used as a criterion for abiogenic origin.

there is a tendency to terminate with propylene, thus producing linear odd and isohydrocarbon homologies⁴⁸. Pyrophoric metal catalysts can also bring about copolymerization reaction⁴⁹. One such catalyst, pyrophoric iron, might have been present in the reducing environment on the primitive Earth. These catalysts have the effect of reducing the reactivity of ethylene relative to propylene by an order of magnitude; on reduced cobalt catalysts they appear to react at the same rates⁴⁹.

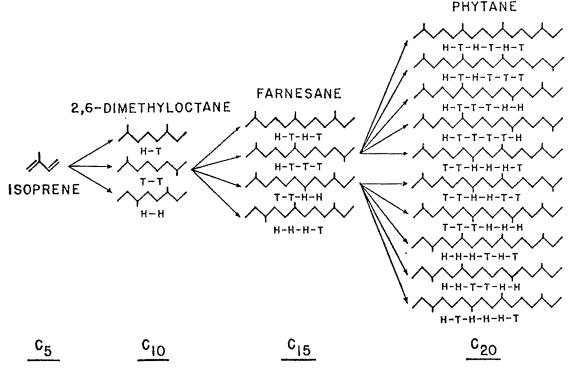

Fig. 1. Polymerization of isoprene.

The copolymerization of the simple olefines and diolefines ethylene, propylene, butadiene and isoprene⁴⁷—which are produced in the thermal cracking of ethane and propane can lead to polymeric products which have methyl groups located at irregular intervals along the linear polymer chain. If the non-biogenic polymerization of isoprene with reduced metal catalysts is invoked to explain the occurrence of polyisoprenoid compounds it is to be expected that copolymerization reactions would have occurred simultaneously. The polymeric products of these copolymerization reactions might serve as a criterion, therefore, of abiogenic origin. The structure of these products might be predicted from what is already known about copolymerization reactions. Ethylene is by far the most reactive of the simple olefines and will be the major constituent of the resulting product. The nature of the transition metal compound has been shown to have major control over the monomer composition of ethylene-propulene copolymers prepared with Ziegler-Natta propylene copolymers prepared with catalysts⁴⁸. Two examples are given below:

 $\begin{array}{c} & \text{Ethylene}(r_1)-\text{Propylene}(r_2) \\ \text{With } Al(\text{Et})_2 \\ \text{TiCl}_4 \\ \text{VCl}_2 \\ \end{array} \begin{array}{c} 38.7 \\ 1,040 \\ \end{array}$

Such polymerization products would be virtually straight chain in character with the occasional methyl branch and

Other criteria for biogenic origin such as the odd to even distribution of normal alkanes are only reliable for most recent sediments. The identification of "biological markers", other than saturated isoprenoid hydrocarbons, within a given organic extract is a reliable criterion in complementing the evidence for biological origin. Except for the porphyrins, however, and the steranes and triterpanes, other classes of "biological markers" do not survive into the most critical region of interest, the Pre-Cambrian, which imposes a severe limitation on this approach. The finding of homologous series in crude oils and sediments, while not in themselves necessarily indicative of biological origin, does augment the evidence for the isoprenoid hydrocarbons, when identified in the same extracts. A further point, which is often not sufficiently emphasized in establishing criteria for biogenic origin, is the relative amounts in which these isoprenoid hydrocarbons are found. In almost all cases they constitute the major components of the "branch-cyclic" hydrocarbon fraction; an observation which argues strongly for a biogenic origin.

Yet another criterion for biogenic origin is the carbon isotope ratios of the organic extract. This approach is based on the fact that photosynthetic organisms discriminate against carbon-13 in preference for carbon-12 (refs. 50, 51). Although not always definitive such measurements on organic extracts have already cast some doubt on certain proposals for an abiogenic origin of the hydrocarbons from hydrothermal deposits. Further insights into this problem might also be obtained from a development of the carbon

isotope approach. The study of the carbon isotope ratios of individual molecules is still rudimentary52 and the experimental problems involved can be overcome. This is a new field of study which could provide valuable information in ascertaining the origin of hydrocarbons.

The problem of the origin of the isoprenoid hydrocarbons remains inconclusive. The evidence still indicates that isoprenoid hydrocarbons are, in most cases, derived from biological sources, even in the Pre-Cambrian samples. It is in this geological time period, however, that we are looking with renewed interest for the transition between chemical evolution and the advent of biological systems. Natta has already demonstrated an experimental, nonbiogenic route to the isoprenoid compounds. The possibility of non-biogenic isoprenoid hydrocarbons is a very real one, and criteria must be established which will distinguish between those derived from an abiogenic origin and those derived from biological systems.

The work described here was sponsored in part by the National Aeronautics and Space Administration and in part by the US Atomic Energy Commission.

Catenated Circular DNA Molecules in HeLa Cell Mitochondria .

bу

BRUCE HUDSON JEROME VINOGRAD

Norman W. Church Laboratory for Chemical Biology, California Institute of Technology

Closed circular mitochondrial DNA molecules which are catenated, or connected like the links in a chain, have been identified in extracts of HeLa cells.

MITOCHONDRIAL DNA from a variety of organisms has been shown to occur in the form of closed circular duplex molecules with a uniform length of about 5μ and a molecular weight of 10 million daltons¹⁻³. Closed circular duplexes display a variety of special properties which arise from the inability of the two polynucleotide strands to unwind. One of these properties, the restricted uptake of the intercalating dye ethidium bromide (EB)4, forms the basis of a convenient method for isolating and detecting closed circular DNA molecules. When this method was first applied in a study of extracts of HeLa cell mitochondria, a paucidisperse system of closed circular molecules was seen in the electron microscope⁵. micron dimers accounted for 10 per cent of the molecules; higher oligomers were present in smaller amounts. The structure of these oligomers, however, was not determined, and it was possible that they consisted of monomers that were joined to each other after extraction of the DNA from the mitochondria. We now report experiments which show that mitochondrial DNA dimers and higher oligomers are stable, isolable DNA molecules that consist of independent, double stranded, closed circles that are topologically interlocked or catenated like the links in a chain. Because of the nature and stability of this topological bond, these oligomers must exist in the HeLa cell. A plausible mechanism for the formation of the catenated molecules is the physical recombination or crossing over of circular mitochondrial DNA molecules.

When ethidium bromide binds to DNA, the strands in the Watson-Crick duplex partially unwind. The unwinding results in a rotation of the molecule about the duplex axis if the DNA is linear or if it is circular and has a single-strand scission or nick. We will refer to both of these types of molecules as open molecules and to closed circular molecules as closed. A closed DNA with no site for rotation resists the uptake of dye in high concentrations and thus binds a smaller amount of dye than an open DNA. The binding of ethidium bromide, which has a low density, lowers the buoyant density of DNA in caesium chloride density gradients. The differential binding causes the closed DNA to band at a higher density than the open DNA. A mixture of closed and open DNAs forms two well separated bands after centrifugation of a mixture of ethidium bromide, caesium chloride, DNA and water. A compound molecule consisting of one closed and one nicked circular DNA would be expected to form a band approximately midway between the closed and open bands.

A fluorescence photograph of an ultracentrifuge tube containing mitochondrial DNA from HeLa cells and nuclear DNA from a subcellular fraction enriched with mitochondria is shown in Fig. 1a. The DNA-dye bands stand out over the background of dye because of the enhanced efficiency of fluorescence when the dye binds to DNA⁶. The positions of the upper and lower bands correspond to the previously reported⁶ positions for open (upper) and closed (lower) DNAs in the conditions used. The middle band, as shown in the microdensitometer record of this photograph (Fig. 1b), is about equally distant from the centres of the upper and lower bands. When examined with the electron microscope, the bottom band was seen to contain about 10 per cent dimers and 90 per

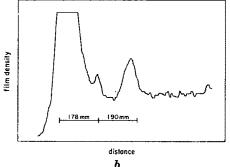

Fig. 1. A caesium ohloride—ethidium bromide density gradient showing the resolved species of HeLa DNA. a, Proparative tube photographed in ultraviolet light through an ultraviolet filter with a Polaroid camera as described* but with type 46 film. The darkest band contains the open DNA. The next two bands in descending order contain the open-closed dimers and the fully closed species. The lowest band is a carbohydrate as judged by the density, turbidity and low dye binding. b, Microdensitometer tracing of this photograph showing the band positions. The left-hand side of the tracing corresponds to the upper part of tube. HeLa S3 cells were grown in suspension culture in Eagle's medium containing 10 per cent calf serum, washed in TD buffer (0·005 M tris, 0·15 M NaCl, 0·005 M KCl, 0·001 M NaH, PO₂), suspended in 0·01 M tris, 0·01 M KCl, 0·005 M KCl, 0·001 M NaH, PO₂), suspended in 0·01 M tris, 0·01 M KCl, 0·005 M KCl, 0·001 M NaH, PO₂), suspended in 0·01 M tris, 0·01 M KCl, 0·005 M KCl, 0·001 M NaH, PO₂), suspended in 0·01 M tris, 0·01 M KCl, 0·005 M KCl, 0·001 M NaH, PO₂), suspended in 0·01 M tris, 0·01 M KCl, 0·005 M KCl, 0·001 M NaH, PO₂), suspended in 0·06 per cent sodium dodecy sulphate—0·01 M EDTA. After 2 h at room temperature enough 7 M CsCl was added to make the solution 1 M in CsCl; it was cooled to 0° C, and centrifuged at 10 K r.p.m. for 30 min to remove most of the caesium dodecy! sulphate—0·10 M EDTA. After 2 h at room temperature enough 7 M CsCl was added to make the solution 1 M in CsCl; it was cooled to 0° C, and centrifuged at 10 K r.p.m. for 30 min to remove most of the caesium dodecy! sulphate. The supernatant was adjusted to 1·56 g/ml, with solid CsCl, and ethidium bromide was added to 200 μg/ml. A sample (3-5 ml.) was centrifuged in a Spinco SW 50 rotor at 43 K r.p.m. at 20° C for 36 h. The bottom and middle hands from four preparations, 3 ml. of packed cells each, were pooled, stored at ~70° C for 1-3 weeks and rebanded to obtain the tube shown. A significant fraction of top band

cent monomers, and the middle band about 60 per cent dimers and 40 per cent monomers. Higher multiples were not included in this count. The dimers contained crossover points at or near the middle of the molecule. Representative electron micrographs of DNA molecules from the middle band are shown in Fig. 2. Dimers were observed on sparsely populated grids. Some dimers were made up of one extended molecule joined to one twisted molecule as shown (Fig. 2c).

We conclude from these observations that the middle band contained joined molecules in which one molecule is a closed circular duplex and the other a nicked circular duplex. The presence of monomers in the middle band is accounted for by the overlap inherent in the breadth of the bands (Fig. 1b) and the size of the fraction taken for electron microscopy. When middle and lower bands from several experiments were pooled and rebanded after some nicking had occurred, the fractional amount of material in the middle band increased substantially while the material in the lower band decreased. Repetition of this procedure resulted in a loss of middle band material. These experiments allow us to dismiss the possibility that the middle band consists of dimers banded at the intermediate position because of a different content of guanine and cytosine.

Measurements of the DNA molecules in electron micrographs made from the middle band (Fig. 3) show that the dimers consist of two molecules both the length of the unjoined monomers. The approximate 5μ length of these molecules from subcellular fractions enriched with mitochondria indicates their mitochondrial origin. The hypotheses that dimers consist of pairs of unequal length or of two populations containing long pairs and short pairs were tested with the χ^2 test and were found not to be statistically significant. The dimers, therefore, consist of two monomeric mitochondrial molecules joined together so that one monomer may be nicked while the other remains closed. The dimers found in the lower band contain joined monomers which are both closed.

The joint between the two molecules is stable in 4.5 molar caesium chloride and survives the hydrodynamic and surface forces which develop when specimens are being prepared. We now consider two possible kinds of joints between the monomeric constituents. kind involves ordinary chemical bonds, either covalent or secondary, between the two constituents, and possibly including joining agents such as proteins. The alternative is that the circular monomers are joined by a topological bond formed by interlocking the two circular monomers. The electron micrographs of dimers from the middle band (Fig. 4) show the interlocked nature of the joint. The molecules were successively shadowed while the specimen was rotated and then while stationary. This procedure reveals the three dimensional details of the two overlaps that are involved in the topological bond. We conclude from photographs of this type that the dimeric mitochondrial molecules are topologically linked circular monomers.

Many rotary shadowed dimeric molecules were examined and they gave the following further evidence that dimers are not joined by ordinary chemical bonds. two intersections between the monomers appeared, under the electron microscope, to be overlapping fibres when the focus was varied about the setting for best focus. In most cases the relations among the levels of the fibres at the two intersections showed that the monomers were interlocked. (b) Photographs of fourteen molecules like those in Fig. 2 were carefully examined by us and by six other people in the laboratory; everyone agreed that there were seven molecules which were catenanes. The rest of the molecules were ambiguously identified (the two possible orientations at each intersection were chosen about equally often). In no case was there agreement that a test dimer represented overlapped molecules. The agreement in the assignment at each crossover was based on

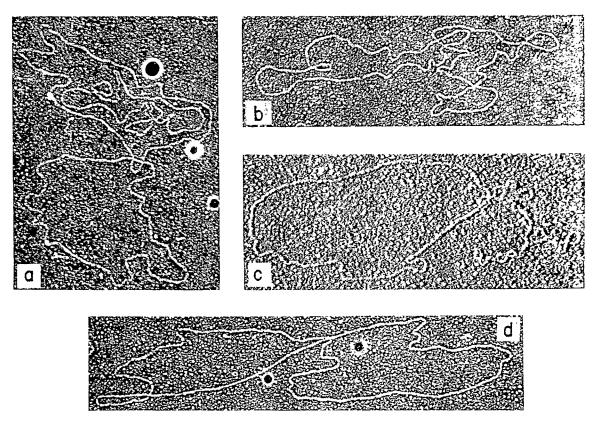

Fig. 2. Representative dimeric molecules from the middle band shown in Fig. 1. The density gradient shown in Fig. 1 was fractionated into approximately 50 μ L fractions. In these conditions the tenth fraction below the centre of the open band contains the peak fraction of the closed band⁴. In this experiment the resultant fractions were diluted with 20 μ L of 10 mg/ml, of cytochrome c and 80 μ L of 0·01 M EDTA, pH 7, and specimen grids were prepared by the procedure of Kleinschmidt and Zalni' with 'Pariodion' covered 200 mesh grids. The hypophase was 0·15 M ammonium acetate, pH 7·4. The DNA-cytochrome films were aged for 10–30 min. The grids were shadowed while rotating with platinum-palladium (except c which was also shadowed from a single direction) and examined in a Philips EM 200 electron microscope. The molecules shown were found in the sixth fraction from the open band. The fourth fraction showed a predominance of the molecules shown in Fig. 5. The eleventh and twelfth fractions contained mostly 5μ monomers with only 10 per cent dimers. (× c, 20,600.)

the continuity or lack of continuity of a light halo (absence of grains) along the edges of the fibres. This halo may be a result of the gathering of the cytochrome from the bulk of the film on to the DNA. (c) Both overlaps otherwise had the same appearance, and the fibres at the joint were not thickened as might be expected if they were held by large protein joiners. (d) Except when the molecules appeared to be pulled from each other and contained only one overlap, there were never sharp corners at the critical overlaps as would be expected if the fibres were joined by mechanically restrictive chemical bonds. From the foregoing we have concluded that at least most of the dimers contained in the middle band (Fig. 1) are catenanes. Our use of the term catenane to describe these compounds follows the usage of Wasserman⁸. The term concatenate has been used to describe oligomers of DNA of unknown structure⁹.

Higher oligomers, n > 2, were also reported previously⁵ and have been found in this study in the lower band and at a higher frequency in the middle band. Trimers, tetramers, pentamers and a septamer have been found, and some examples are shown in Fig. 5. The interlocking nature of these molecules was confirmed by examining the photographs and in some cases by focusing the electron microscope.

We have considered the possibility that accidental overlapping of molecules could result in apparent catenation. Such accidental overlaps occur only infrequently for circular molecules of this length. We have examined photographs of polyoma circular DNA (1.5μ) , and λ phage circular DNA (15μ) as well as mitochondrial DNA, and have found that even at high surface concentrations the DNA molecules seem to avoid one another (Fig. 2a) rather than overlap. A plausible explanation for this

effect is that the complex of DNA and cytochrome is able to move at the surface of the hypophase. Because the DNA-cytochrome films are allowed to age for from

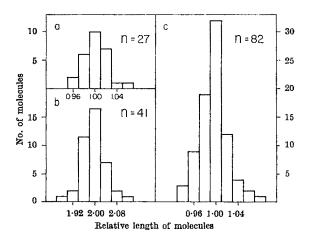

Fig. 3. Length measurements of mitochondrial DNA molecules from the middle band shown in Fig. 1a. Single length (monomeric) molecules. The approximately 5μ lengths were normalized by the mean length for the population. The standard deviation was 2·1 per cent. b, Double length (dimeric) molecules. The lengths were normalized by the factor used in a. The normalized mean length was 1·994 with a standard deviation 2·2 per cent about 2·000. c, Monomeric units contained in dimers. The lengths were again normalized by the mean length of monomers in a. The mean length was 0·997 with a standard deviation of 2·5 per cent about 1·000. The normalization procedure reduces the effect of drift in the magnification factor and stretching of the 'Parlodion' specimen supports. This latter factor is an important cause of scatter. In effect we are using the approximately 5·3\(\mu\) monomers as internal relative standards in photographs of one grid hole. All these data were obtained with one specimen grid. Results from another grid were quantitatively similar. Length measurements were made on low gloss prints with a map measure.

10 to 30 min, the complexes are able to separate from each other and expose to the surface the most possible protein side groups. Careful examination of the dimers which had been shadowed from one direction showed that only very few apparent dimers were accidental overlaps. There is a phenomenon known as flower pattern formation which causes the aggregation of DNA into large complex structures. Flower patterns were observed infrequently on one or two of the grids and were easily distinguishable from the higher oligomers by their very compact nature.

These catenated molecules represent a new class of naturally occurring compounds. Molecules with topological bonds¹⁰ were first identified by Wasserman⁸, who formed catenated dimers of thirty carbon rings. Wang¹¹ prepared non-covalent catenanes by cyclizing viral λ DNA in solutions containing high concentrations of hydrogen bonded phage 186 circular molecules. Topo-

logically bonded DNA molecules have been known for some time. Monomeric mitochondrial DNA and all other closed circular duplex DNAs contain single stranded DNA molecules which are topologically bonded to their respective complements. The pairs of single rings in closed duplex molecules are interlocked by one topological bond which is characterized by a topological winding number, α , of about 450 in polyoma^{12,13} and SV 40⁴ DNA and about 1,500 in closed circular mitochondrial DNA. The quantity α represents the number of times one strand winds about the other when the molecule is constrained to lie in a plane. The corresponding quantity, A, for interlocked duplexes is unity in all the catenanes described here.

In the discussion which follows the circular duplex will be considered as a single circular system (the individual polynucleotide strands will not be considered). Catenated

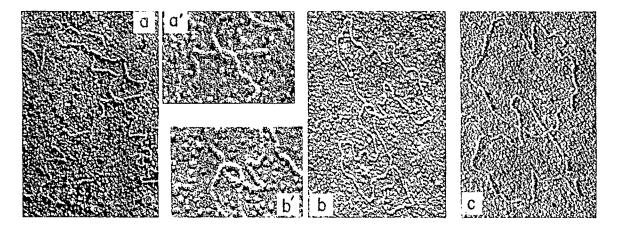

Fig. 4. The interlocking nature of catenated dimers. The specimen grid prepared as described in Fig. 2 was subsequently shadowed from one direction to reveal the three dimensional nature of the intersections. ($\times c$. 18,775 except a' and b' which are $\times c$. 34,600.)

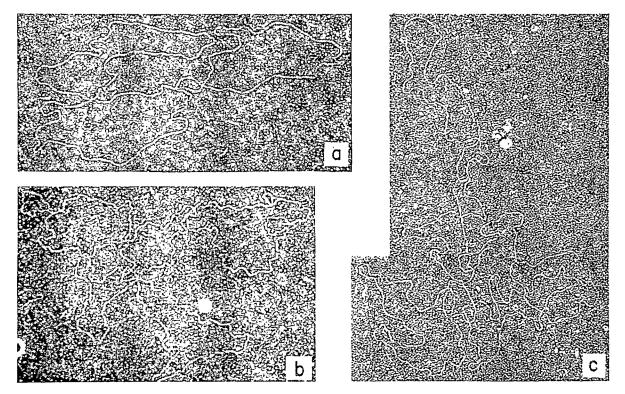

Fig. 5. Higher oligomers of mitochondrial DNA. The specimens were prepared as described in Fig. 2. a, A trimer b_2c . b, A tetramer b_2c_2 . c, A pentamer b_2c_2e . ($\times c$. 20,600.)

trimers differ from dimers in that at least one ring is joined to two others. In a linear trimer two of the molecules have a topological bonding number (TBN) of one, and the third a bonding number of two. All three molecules in the cyclic trimer have a TBN of 2. Isomerism based on the TBN results in a large number of species in the case of higher oligomers. Figure 6 presents the isomers for $n \le 4$ together with a notation system based on the The criterion for determining the TBN is the number of circles that must be cleaved in order to free an intact circle. In this system a stands for TBN=0, b for TBN = 1, and so on. Subscripts indicate the number of monomers of a given topological bonding number in the oligomer. The pentamer shown in Fig. 5c is characterized by the formula b_2c_2e . This system does not specify the topological winding number in the bonds, nor does it distinguish structural isomerism based on the three dimensional arrangement of the topological bond. Figure 7b shows the optical isomers for the cyclic trimer, and

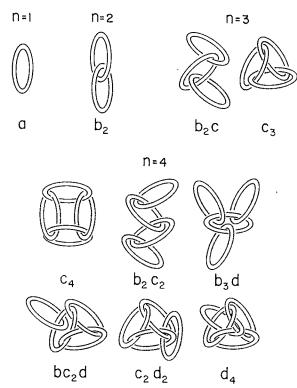

Fig. 6. Topological bonding number (TBN) isomers. The simple connexion of two circles by a single winding (A=1) is regarded as the only type of bond. The formula representations are based on α for TBN=0, b for TBN=1, and so on.

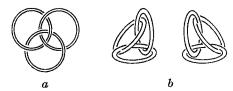

Fig. 7. Examples of topological isomers other than topological bonding number isomers 10. a, A Borromean ring, a trimeric structure with topological bonds based on a linkage type other than simple catenation. b, The pair of enantiomers for one of the c₂ species. There is another pair of enantiomers for a second c₂ species. The latter pair differ from the one shown in the order of the overlaps of the crossings.

Fig. 7a represents a trimer with topological bonds based on a higher type of topological linkage than simple catenation. There is a further type of isomerism, based on the polarity of the strands in the Watson-Crick duplex. which gives rise to two polarity isomers for the catenated dimer and to many further isomers for the higher oligomers.

We now consider the origin of the oligomers in terms of known processes in which the backbone bonds of DNA are formed or re-arranged. We postulate that these molecules arise either in the course of replication or recombination. The mode of replication of closed circular molecules is not yet understood adequately to permit predictions of the possible structures that might be formed as replication intermediates or as a result of errors of replication. The breakage and reunion model for genetic recombination, on the other hand, enables us to formulate a plausible scheme for the formation of the catenated oligomers described. It also enables us to correlate the results presented here with those obtained with mitochondrial DNA from human leucocytes as described in the following article. The model also suggests the existence of structures that have not as yet been The catenated molecules, according to the recombination model, result from a double recombination between two circular mitochondrial DNA molecules. This process could occur as two consecutive single recombination events or as a concerted process in which both recombination events occur within the same pairing region (Fig. 8). Higher oligomers would be formed by double recombinations between a monomer and catenated dimers. Doubly interlocked dimers (A=2) should result from four recombination events. The recombination model for the origin of catenated circles predicts that circular dimers without crossing points should also occur. Such species have been observed at a very low frequency in the bottom (closed) band. It is possible that the low frequency is in part a consequence of the loss of cyclic dimers from the closed band because of statistical nicking. Also, twisted circular dimers are difficult to distinguish from catenated dimers. These circular oligomers of mitochondrial DNA

Fig. 8. The circular mitochondrial molecules first pair (a) and are then "broken" either once (b) or twice (c) as shown. If broken once, reunion results in an open dimer (d) which can pair again (e) and recombine. Half of the products of the second recombination will be catenanes (f) while the other half will be separate circles. If broken twice (c) half of the recombinations will result in separate circles (i) while half will be catenanes (h). Double recombination events between dimeric catenanes and monomers result in trimeric catenanes and this can be continued to higher species.

are more frequent in other systems and are discussed in more detail in the following article. Species involving 10μ circular dimers catenated to 5μ monomers should also be seen but have not yet been observed in mitochondrial DNA of HeLa cells. Double interlocked dimers (A=2) have not as yet been conclusively identified.

The recombination model places the various types of mitochondrial DNA species in a sequence running from circular monomers to circular dimers, to catenated dimers, to higher oligomers. In particular, it predicts that catenated dimers will occur before higher oligomers and that, as catenated dimers increase, circular dimers will decrease. The population of mitochondrial DNA is viewed as an equilibrium population, and the various possible distributions of mitochondrial species as different positions in a multiple equilibrium. The equilibrium position for HeLa cells seems to be well to the right of catenated dimers. Other equilibrium positions are known for human leukaemic leucocytes (see following article).

The sequence of events depicted in Fig. 8 depends somewhat on the particular mechanism of the recombination process. An alternative mechanism which has been proposed, does not involve the initial formation of a four-stranded pairing region between the duplex molecules. Instead the molecules are specifically broken, matched with another specifically broken molecule and reunited. Reciprocal recombinants are not formed in the same recombination event but are statistically equally likely. The ends of the molecule are free to move in solution. The most reasonable proposal for the specific recognition system for the matching of the broken molecules is that the initial breakage gives rise to single stranded cohesive ends on the two fragments. This model of the recombination event differs from the homologous pairing model (Fig. 8) in that catenated dimers can arise from monomers without the intermediate formation of a cyclic dimer. If linear molecules with cohesive ends are formed in low concentration and then recyclize in the presence of closed circles some catenanes will form. According to this model catenanes are only a by-product of recombination; the two members of a dimer have not undergone a recombination event with each other. In conditions of high concentrations of linear molecules with cohesive ends, cyclic dimers would form. Another mechanism for catenane and cyclic dimer formation involves the opening and reclosure of mitochondrial DNA molecules at one specific point in the molecule. This process would be similar to the closure and reopening of λ phage DNA and is presumably not related to recombination.

Genetic recombination between cytoplasmic genomes in Chlamydomonas has been demonstrated in the experiments of Sager¹⁴. Possibly the observed fusion of mitochondria in the cytoplasm¹⁵ is a manifestation of a recombination event. Interaction between the mitochondria of different strains of maize has been reported to result in a new type of mitochondria in the hybrid strain¹⁶. On the other hand, because the number of DNA molecules in specific mitochondria is not known, it is possible that the recombination process described here could occur between molecules in each mitochondrion. Our results show that in some mitochondria, possibly those which are structurally or functionally abnormal, there are at least two to seven mitochondrial-length molecules. The monomeric units of the oligomers described here are all the same length and have approximately the same base composition and are therefore, probably identical genomes. Polymerization of mitochondrial DNA molecules may result in gene duplication which would otherwise not occur.

We thank S. Hudson for printing electron micrographs and measuring the molecules; L. Wenzel, C. Phillips and J. Eden for their assistance in the preparation of HeLa cells; P. Koen for assistance with the electron microscope; and R. Kent for assistance in the preparation of the manuscript. This work was supported in part by grants from the US Public Health Service.

Circular Dimer and Catenate Forms of Mitochondrial DNA in Human Leukaemic Leucocytes

DAVID A. CLAYTON JEROME VINOGRAD Norman W. Church Laboratory for Chemical Biology, California Institute of Technology

Oligomer forms of circular mitochondrial DNA have been identified in mitochondrial extracts of human leukaemic leucocytes. The oligomers occur as circular dimers with a contour length of $10 \, \mu$ and catenanes made up of interlocked 5μ monomers.

MITOCHONDRIAL DNA from a variety of organisms¹⁻³ has been reported to occur in the form of covalently closed circular duplex molecules approximately 5μ in contour length. These cytoplasmic DNAs resemble polyoma viral DNA4 in several physical chemical properties that are shared by all closed circular DNAs. One such property, the restricted uptake of the intercalating dye ethidium bromide (EB), forms the basis for a convenient centrifuge method for isolating substantially pure mitochondrial DNA7. The finding in this laboratory that HeLa cell mitochondrial DNA preparations obtained by ethidium bromide method contain 10 per cent multiple length molecules, or oligomers prompted us to examine the structure and size distribution of mitochondrial DNA in preparations from animal cells in a variety of physiological states. This report presents the result that mitochondrial DNA from human leukaemic leucocytes contains circular dimers, closed circular duplex DNA molecules

Fig. 1. A caesium chloride—ethidium bromide density gradient showing the two bands obtained with mitochondrial DNA preparations from leucocytes of the chronic granulocytic leukaemic patient, M.C., from March 8 to May 20, 1967. The 3 ml. solution of DNA in caesium chloride at a density of 1-55 g/ml., and 100 \(\textit{\mu}g/ml\) of ethidium bromide, \(\textit{\mu}H = 8-0\), was centrifuged 36 h at 43 K r.p.m. and 20° C in an SW 50 rotorin a Beckman \(L^2 = 65B\) ultracentrifuge. The preparative tube was photographed in near ultraviolet light. In the usual procedure a 500 ml. unit of blood was withdrawn into ACD. The inverted bottle was stored for 3 h in the refrigerator and the red cells were re-infused. The leucocytes and the remaining plasma were then chilled to 4° C. The leucocytes were spun down and resuspended in the homogenizing medium, 0.01 M KCl, 0.01 M tris chloride, 0.005 M Na EDTA, pH 7-5. After homogenization with a tight fitting "Teflon" pestle, sucrose was added to 0.25 M, and the nucle and cell debris removed by centrifugation at 3 K r.p.m. in an SS34 Sorvall rotor for 5 min. Resuspension and centrifugation were repeated. A greenish material, presumed to contain myeloperoxidase, was then pelleted at 5 K r.p.m. for 5 min. The mitochondrial DNA and linear nuclear DNA. The lower band contains closed circular mitochondrial DNA, the threshold level of detection in visible light of a DNA—EB band, from 5 × 10° leucocytes. The recovered material corresponds to 600 mitochondrial DNA molecules in a mitochondrion vary between two and six in different organisms. On the basis of these results we calculate that the lower bands contain 15–50 per cent of the mitochondrial DNA in the cell population.

approximately 10 μ contour length. The preparations also contain catenated dimers, interlocked pairs of 5 μ closed circular DNAs, such as have been shown to occur in HeLa cell mitochondrial preparations (preceding article).

Leucocyte samples were obtained at approximately weekly intervals from the chronic leukaemic (M. C.). Samples from the lower band (Fig. 1) obtained at the beginning of this study were pooled and recentrifuged. The lower band contains the intact mitochondrial DNA molecules which exhibit restricted dye uptake. Examination of the DNA molecules from the lower band in the electron microscope revealed that 26 per cent of the molecules were circular dimers (Table 1). Fig. 2 presents electron micrographs of the types of molecules found. Only 3 per cent catenated dimers and 2 per cent trimers were observed. In addition to the molecules which were scored (Table 1) from prints of fields with high contrast and showing molecules with few overlaps, several thousand molecules were viewed under the electron microscope and scored for the fraction of total dimers This percentage of circular dimers was confirmed by the sedimentation velocity analysis described The histograms (Fig. 3) demonstrate that the dimers have twice the contour length of the monomers.

We note that 49 per cent by weight of the mitochondrial DNA in the lower band obtained from this patient (M. C.)

is in the form of oligomers, and for the most part in the form of circular dimers. It is not yet possible to relate this number—probably a minimum—firmly to the distribution in the leucocytes of the donor. The frequency of oligomers, f, will be affected by any process of selection for or against closed oligomers over closed monomers. The following processes lead to selection if they occur to a significant degree. (a) An incomplete recovery of mitochondria from the different cell types biases the results is the cell types contain different amounts of the variouf oligomer species. Inspection in the light microscope of homogenates stained with azure C revealed that all cell types were effectively disrupted. This effect is therefore not likely to be significant. (b) Hirt11 has shown that very high molecular weight nuclear DNA is spun down with the sodium dodecylsulphate (SDS) precipitate in the isolation procedure. It is conceivable that some very high oligomers may have been lost, and that f was reduced. (c) In the approximately 4 h period between withdrawal of whole blood and the disruption of the mitochondria, nuclease may have been active within the mitochondria. We have no way of assessing this effect, except to note that we have recovered approximately 15-50 per cent of the mitochondrial DNA as closed DNA. (d) After the SDS treatment all the mitochondrial molecules are in a common environment and subject to nicking by reducing agents and active endonucleases that may be present. Because the oligomers are the larger targets, f may have been reduced. Barring an enhanced stability of the oligomers over the monomers in the mitochondria, after withdrawal of blood, the estimates of the frequency of oligomers f (Table 1) are considered to be minimal.

The physical chemical properties of this new form of mitochondrial DNA, the circular dimer, were studied by means of ultracentrifugation. The material from the lower band diluted with an equal volume of twice distilled water and freed of dye by chromatography through a 50 µl. bed volume of 'Dowex-50' cation exchange resin was examined by the band sedimentation velocity procedure12 in 2.85 molar caesium chloride (Fig. 4). The standard sedimentation coefficients calculated for sodium DNA for the three components are $51 \pm 1.4S$, $36.5 \pm 0.8S$, and 26.9 ± 1.7S. Similar experiments in alkaline 2.85 molar caesium chloride showed two discrete components with incorrect sedimentation coefficients of 112S and 80S (Fig. 5). Figure 6 presents a double logarithmic plot of sedimentation coefficient against molecular weight for closed circular DNA with additional data obtained from the literature. The 80S and 112S alkaline components fall on the line for closed circular DNA in alkali. The slow 27S species at neutral pH falls on the line II for nicked circular DNA. The fast 51S component falls above the line I for in vivo closed circular viral DNA at neutral pH, as do all other mitochondrial DNAs so far reported. We conclude that the neutral 51S component represents the compact superhelical form of the circular dimer. 80S and 112S components in alkali represent the fully titrated forms of the closed monomer and dimer respectively. The intermediate 37S component is apparently a mixture of nicked dimers and intact monomers. Figure 6 indicates that the closed monomer should sediment slightly faster than the nicked dimer.

We have calculated from the fractions of intact dimer and nicked monomer observed in Fig. 4 that the original

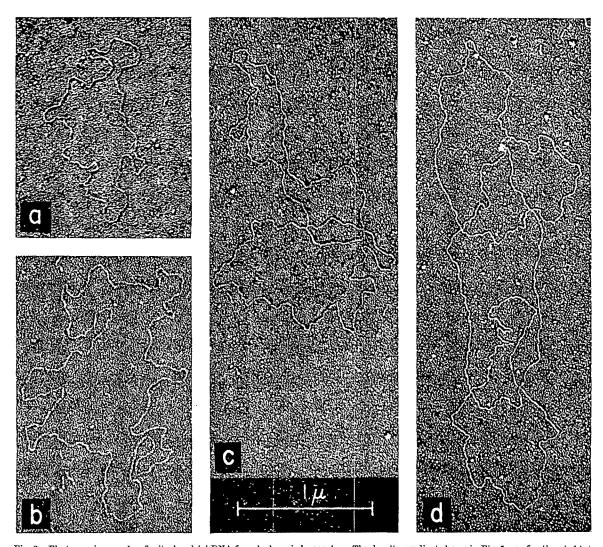

Fig. 2. Electron micrographs of mitochondrial DNA from leukaemic leucocytes. The density gradient shown in Fig. 1 was fractionated into approximately fractions of 50 μl. and specimen grids were prepared with material found ten to twelve fractions below the centre of of the upper band. A sample 125 μl. of the fraction was diluted with 30 μl. of 1 mg/ml. of cytochrome c and 40 μl. of 0.01 M EDTA, pH 8-0. The specimen grids were prepared by the procedure of Kleinschmidt and Zahn¹o with 0.15 M NH,Ac, pH 7-4, as the hypophase. The grids were shadowed while rotating with platinum-palladium and examined in a Philips EM 200 electron microscope. a, Single length mitochondrial DNA; b, circular dimer form; c, catenated timer; d, catenated timer. The catenation was established by focusing at the microscope and by careful examination of the negatives as described by Hudson and Vinograd (preceding article).

lower buoyant band contained 33 per cent dimers. The calculation was carried out with the assumption that statistical nicking occurred after the band was isolated. The agreement between this result and that obtained by electron microscopy (29 per cent, Table I) suggests that there was no significant selection for or against dimers in the specimen grid preparation or in the electron microscope examination.

Further evidence that the 51S component represents a closed circular dimer form was obtained by analytical ultracentrifugation. Mitochondrial DNA recovered from the experiment described in Fig. 4 was centrifuged to equilibrium in buoyant caesium chloride containing ethidium bromide. Conditions were selected so that the closed DNA was separated from the open DNA in the caesium chloride-ethidium bromide gradient. The ratio of amounts of closed to open DNA in the buoyant gradients was 0.5, compared with 0.75 expected for this material in the absence of further nicking. If, on the other hand, the leading component had consisted of nicked dimer and closed monomer, the middle component of nicked monomer, and the slow component of linear DNA, the ratio would have been 0.15.

The buoyant densities of the dye-free mitochondrial and nuclear DNA differed by 0.010 g/ml. (Table 2) in separate experiments with a crab dAT marker. The increment was

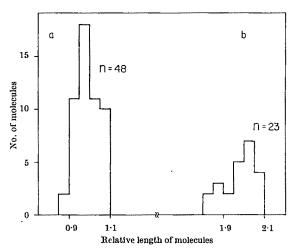

Fig. 3. Normalized contour lengths of mitochondrial DNA from the lower band in a caesium chloride-ethidium bromide density gradient. The DNA was obtained from leucocytes from the chronic granulocytic leukaemic patient, M. C. a, Single length molecules. The approximately 5μ lengths were normalized by the mean length. The standard deviation was ± 0.05 dimensionless units. b, Double length molecules which were predominantly circular dimers. The approximate 10μ lengths were normalized by the mean monomer length. The standard deviation was ± 0.06 dimensionless units.

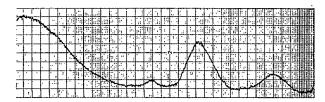

Fig. 4. Band sedimentation velocity pattern of originally closed mitochondrial DNA from M. C. in 2.85 M caesium chloride, pH 8-0, 20° C. Photoelectric scan of the liquid column 40 min after reaching 30 K r.p.m. The field is directed to the right. The leading band contains the 51S closed circular dimer. The middle band contains the 37S unresolved mixture of nicked circular dimer and closed circular monomer. The slowest band contains the 27S nicked circular monomer. The absorbing material between the slowest band and the meniscus is EDTA. No material sediments from this region after longer times at higher speed.

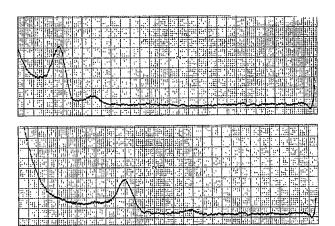

Fig. 5. Band sedimentation velocity pattern of originally closed mitochondrial DNA from M. C. in 2.85 M caesium chloride, pH 12.3, 20° C. Photoelectric scans of the liquid column at 8 min intervals at 28 K r.p.m. The fast band contains the 1125 fully titrated closed circular dimer. The slow band contains the 805 monomer. At higher speeds a broad 265 band sediments out of the region obscured by the absorption of light by EDTA.

also observed in a synthetic mixture of mitochondrial and nuclear DNA (Fig. 7). The buoyant densities of nuclear DNA from leukaemic and normal leucocytes were indistinguishable. The mitochondrial DNA, containing 39 per cent by weight circular dimers, formed a symmetrical buoyant band in caesium chloride in the analytical ultracentrifuge. This result proves that the circular dimer has about the same base composition as the circular monomer and suggests that circular dimers consist of two connected monomer genomes. The clinical and diagnostic data for M.C. and the other two patients in this study are shown in Table 3.

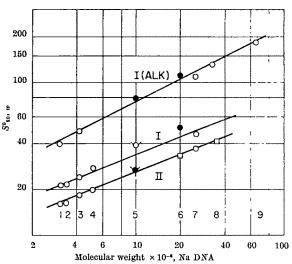

The mitochondrial DNA from leucocytes from the sub-acute granulocytic leukaemic (S.T.) formed three fluorescent bands (Fig. 8). The lower band contained 9 per cent dimers, of which approximately 60 per cent were catenated dimers (Table 1). A histogram of 277 molecules is presented in Fig. 9. We do not regard the difference in oligomer content between M. C. and S. T. as significant

Table 2. Buoyant densities of mitochondrial and nuclear dna from normal and leuraemic human leucocytes on caesium chloride at $25^{\circ}\,\text{c}.$

	'	•	No. of
Source	Nuclear	Mitochondrial	experiments
М. С.	$1.689, \pm 0.0002$	$1.700_0 \pm 0.0003$	3
S. T.	1.689	1.700	i
S. B.	1.689	1.700	ï
Normal donors	1.6895		ĩ

Buoyant densities were calculated from the distances between the above DNAs and a crab dAT marker. In these calculations the buoyant density of the marker was taken to be $\theta=1.669_0$, a value determined by the absolute method. The buoyant density gradient, Vinograd and Hearsi's, was used in the calculations. If these buoyant densities are calculated with an assumed value of 1.710 g/ml. for an $E.\cos DNA$ marker and with a gradient uncorrected for the effects of pressure, the buoyant densities of the nuclear and mitochondrial DNAs are 1.6954 and 1.7055, respectively. These values correspond to a G-C content of 36 mole per cent for nuclear DNA and 46 mole per cent for mitochondrial DNAs.

because the time between the withdrawal of blood and homogenization was 10 h for S. T. compared with 4 h for M. C., and extensive nicking may have occurred. The middle band was midway between the closed and open DNA bands. This position corresponds to the expected

Molecular weight × 10-4, Na DNA

Fig. 6. Sedimentation coefficients of three forms of circular DNA as a function of molecular weight. The results for the fully titrated mitochondrial circular monomer and dimer and for the neutral nicked monomer fall on the best least squares lines for data previously published or in the press. The alkaline sedimentation coefficients represent partially corrected values obtained from experiments at 20° C in approximately 2·85 M caesium chloride, 1·35 g/ml. The data were corrected only for the small effects of solution density when the concentration of caesium chloride departed from the above value. The least squares slope of this line is 0·49. The neutral standard sedimentation coefficients were measured at 20° in caesium chloride or sodium chloride and when necessary have been corrected by the method of Bruner and Vinograd. The slopes for the closed circular DNA, I, and the nicked circular DNA, II, as determined by a least squares method are 0·38 and 0·39. 1, Polyoma⁴; 2, RF φX174 (ref. 14); 3, RF M13 (ref. 15); 4, human papilloma¹⁵; 5, mitochondrial monomer (ref. 2 and unpublished work of Vinograd. Fig. 7. Photoelectric scan of a synthetic mixture of nuclear and mitochondrial leucocyte DNA from the patient M. C. in neutral buoyant caesium chloride; 25°C, 44 K.r.p.m., Moseley X-Y parallel recorder. The field is directed to the right. The light band contains crab dAT, the middle and dense bands contain nuclear and mitochondrial DNA, respectively.

position for a catenane containing one open and one closed molecule as described for HeLa cell mitochondrial DNA.

The catenane index, the ratio of catenated dimers to total dimers, varies by a factor of six between the preparations from M. C. and S. T. This index for the DNA in the lower band is representative of the index at the time of dissolution of the mitochondria by SDS, and is insensitive to the extent of statistical nicking that may have occurred.

In extreme cases it was easy to discriminate between circular dimers and catenated dimers, but molecules that contained several crossovers were often not scored. Completely open molecules or molecules in which the crossovers occurred only near the ends of the molecules were scored as circular dimers. Dimers consisting of an open monomer and a twisted monomer, dimers with only one crossover which divide it into statistically valid halves, and dimers in which the three dimensional character of the catenation could be seen in the electron microscope or the prints8 were scored as catenanes. We have made the assumption that highly twisted catenanes and circular dimers were rejected with the same probability. catenane index is the best available basis for comparison of the different DNA preparations that we have investigated.

The mitochondrial DNA from the case of chronic lymphocytic leukaemia (S. B.) also formed three fluorescent bands in the caesium chloride ethidium bromide gradient. The DNA in the lower band contained 5 per cent oligomers, of which approximately half were catenated molecules (Table 1, Fig. 9). There was 24 h between the withdrawal of blood and homogenization in this patient, and so the oligomer content may be artificially low.

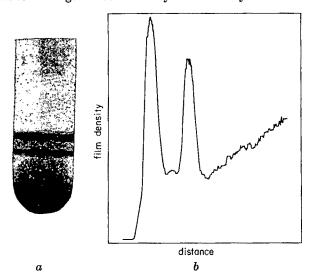

Fig. 8. a, Fluorescence photograph of a caesium chloride-ethidium bromide density gradient as in Fig. 1. b, A microdensitometer tracing showing band positions. The left hand side of the tracing corresponds to the upper part of the tube. The middle band indicates the presence of catenated dimers as shown by Hudson and Vinograd in the preceding article.

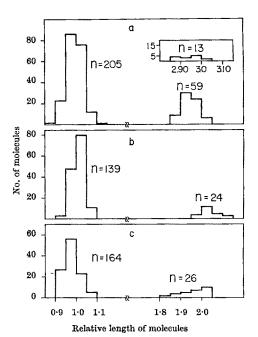

Fig. 9. Histogram of normalized contour lengths of mitochondrial DNA from the lower band in a caesium chloride-ethidium bromide density gradient as in Fig. 3. a, DNA from S. T.; b, DNA from S. B.; c, DNA from normal donors.

The closed mitochondrial DNA from leucocytes of normal donors was examined with material prepared from five samples of fresh blood. Only two fluorescent bands were found. Analyses of the lower band showed that 1.5 per cent of the mitochondrial DNA molecules were dimers (Table 1). A catenane index was not obtained because of the small number of dimers present in the electron micrographs. The period between blood withdrawal and dissolution of the mitochondria by SDS varied between 5 and 12 h.

The results so far can be summarized as follows. (a) Oligomer forms of mitochondrial DNA occur in leucocytes from normal and leukaemic human donors. gomers are principally circular and catenated dimers. Catenated trimers and a very small percentage of catenated higher oligomers also occur. (b) There are differences in the distribution of types of oligomers in the DNA preparations from the three leukaemic patients studied. The preparations from the two patients with clinically more advanced leukaemia (S. T. and S. B.) had a higher catenane index. (c) The circular dimers and catenated dimers represent new forms of mitochondrial DNA. The catenated forms have also been found in HeLa cells (preceding article).

Mitochondrial DNA isolated from M. C. during April to May, 1967, showed only two bands (Fig. 1) while pooled DNA preparations obtained during June to July, 1967, yielded three fluorescent DNA bands. This indicates that

Fig. 10. Formation of oligomers by a postulated breakage and reunion mechanism. a, The circular dimer is formed in a single recombination event between two monomer molecules. b, The catenated dimer could result from a double recombination event between two monomers or a single recombination event within a circular dimer. c, A double recombination event between a catenated dimer and monomer molecule results in the formation of a catenated dimer. This scheme can be continued to form higher oligomers.

there was an increase in the fraction of catenated dimers in the preparations. Electron microscope analysis showed that the fraction of oligomers had remained essentially constant and that the catenane index approximately doubled. The change paralleled a significant shift in the leucocyte population: myeloblasts and promyelocytes increased and there was a corresponding decrease in mature forms.

A genetic recombination pathway based on the breakage and reunion model has been proposed as a possible scheme for the formation of the oligomers described here (Fig. 10) and in HeLa cell mitochondrial DNA (preceding Changes in the equilibrium distribution of oligomers in the leukaemics studied may have resulted either from changes in the proportion of the various cell types or from changes within a given cell type. In either case it seems that there are various equilibrium positions in the monomer-oligomer equilibria.

Other investigations in this laboratory have shown that there are interlocked mitochondrial molecules in a variety of other systems. Mitochondrial DNA of unfertilized sea urchin eggs, for example, contains catenated dimers and a small proportion of higher catenated oligomers (unpublished results of Blair, Pikó and Vinograd). A middle band containing catenated oligomers has been obtained from the mitochondrial DNA of 3T3 mouse cells transformed by SV 40 virus. These results suggest the possibility that oligomers were present but not reported in the mitochondrial DNA preparations earlier described¹⁻³. The elucidation of the relationship between the occurrence of the oligomers and the physiological state of a cell will require further quantitative investigation of a variety of cell systems. The dye-buoyant density method used in this work provides highly purified closed mitochondrial DNA, but as discussed the method selects against open DNA that may be present. In our continuing study of the composition and structure of mitochondrial DNA in normal individuals and in leukaemic patients, nonselective methods are being used to isolate the total complement of DNA in the mitochondria.

We thank Dr H. R. Bierman for providing the leucocytes and for clinical data and diagnoses; L. Clayton for measuring the molecules; Hyland Laboratories, Los Angeles, California, for gifts of normal blood; Dr R. Lewis for haematological data; J. Kiger, J. C. Wang and R. L. Sinsheimer for permission to quote their unpublished results; and W. R. Bauer for his advice. This work was supported in part by grants from the US Public Health Service, and by a Public Health Service fellowship from the National Institute of General Medical Sciences.

Thermal Poly- α -amino-acids containing Low Proportions of Aspartic Acid

by

DUANE L. ROHLFING*

Exobiology Division, Ames Research Center, National Aeronautics and Space Administration, Moffett Field, California

Synthetic poly- α -amino-acids (proteinoids) are prepared by heating together suitable proportions of eighteen common amino-acids. Proteinoids which more closely resemble proteins in amino-acid composition can now be prepared from reactants augmented with lysine and neutral amino-acids.

THE feasibility of preparing poly-α-amino-acids by heating suitable proportions of dry amino-acids has been demonstrated by Fox and associates 1-6. The products of the thermal condensation reactions can range from homopolymers of aspartic acid2 or lysine3 to heteropolymers, termed proteinoids, which contain some proportion of each of the eighteen common amino-acids⁴⁻⁶. Proteinoids exhibit many properties in common with proteins1, and, because they are prepared under geologically plausible

*Postdoctoral resident research associate, US National Academy of Sciences. Present address: Department of Biology, Massachusetts Institute of Technology, Cambridge, Massachusetts.

conditions, they have been regarded as models of abiotic

The amino-acid compositions of proteinoids can in part be regulated in a controllable and reproducible manner⁵⁻⁸. The content of amino-acids in the products reflects, however, the large proportion of dicarboxylic amino-acids or of lysine which is commonly used in the reactants. For example, proteinoids prepared from reactants containing a large proportion of aspartic and glutamic acids typically contain 40-70 per cent aspartic acide; lysine-rich proteinoids, prepared from reactants enriched with lysine free base (as opposed to the hydrochloride salt), contain about

50 per cent lysine⁵. These high proportions of non-neutral amino-acids are not typical of proteins. The proportion of aspartic acid in acid proteinoids has to some extent been reduced by lowering the proportion of aspartic (or aspartic and glutamic) acid in the reactants4,6, but low yields of quite dark products have limited this approach4. method is described here of preparing proteinoids which contain a very low proportion of aspartic acid, using conditions which do not result in diminished yields or dark products. These polymers were obtained from reactants which contained lower proportions of aspartic acid than normally used, but which were augmented with lysine free base. Less satisfactory results were obtained when lysine was omitted or used as the hydrochloride salt. Furthermore, the content of neutral amino-acids in proteinoids containing low amounts of aspartic acid has been considerably increased.

Proteinoids were prepared and processed by a modification of the method of Fox and Harada4, using L-aminoacids. The compositions of the various reactants are given in Table 1. The reactants were heated in an oil bath at 175° C under prepurified nitrogen purge for 3.5 h. After cooling under nitrogen, the crude products were dissolved in normal sodium hydroxide and the resulting solutions were dialysed against running distilled water for 2-3 days and were filtered. The filtrates were acidified to pH 2 and were dialysed for another day. The solutions were again filtered and were then lyophilized. The amounts of insoluble material were quite small; only the soluble, nondiffusible portions were used in later experiments. technique used ensures that the product is purified by true dialysis, rather than by dialytic washing of a suspension; the yields are accordingly lower than those previously reported4.

Samples of proteinoids were hydrolysed, before amino-acid analysis, in constant boiling hydrochloric acid in evacuated, sealed tubes, at 106°-110° C, for 48 h. The analyses were performed on either a Phoenix or Beckman automatic amino-acid analyser. The recoveries of amino-acids, uncorrected for ash or moisture content, were usually about 70 per cent, although a progressive drop in recovery was found in Series A as the proportion of aspartic acid in the polymer decreased. Clear trends in the contents of histidine, arginine and individual neutral amino-acids were not evident, and these have not been separately reported; tryptophan, destroyed by acid hydrolysis. but shown previously to be incorporated into proteinoids, was not determined. The absorption spectra of proteinoids in 0·1 normal acetate buffer, pH 5·0, were determined on a Turner model 210 spectrofluorimeter,

used as a spectrophotometer. The absorption increased rapidly as the wavelength decreased in the range 400–300 mµ; a slight shoulder occurred near 350 mµ, and this wavelength was used to evaluate relative intensities of colour. Optical rotations at the sodium D line, using about 5·0 mg polymer/ml. in 0·067 molar phosphate buffer, pH 6·8, were determined using a Rudolph model 80 photoelectric polarimeter equipped with an oscillating polarizer. Estimates of relative molecular size were made using a 'Bio-Gel P-4' column. The values reported are the percentages of the total sample (determined by the optical density at 220 mµ) which eluted from the column in the same volume required for the elution of bovine albumin. The solvent was 0·1 normal in acetic acid and sodium chloride.

The polymers of Series A (Table 1) were prepared from reactants in which the proportion of aspartic acid was progressively lowered. Lysine was not present, except for the $0\cdot16$ g contained in the equimolar mixture of basic and neutral amino-acids. As the amount of aspartic acid in the reactants decreases, the proportion in the product decreases to 40 per cent. This decrease is accompanied, however, by an increase in the proportion of glutamic acid, such that the content of both dicarboxylic amino-acids is reduced by only 11 per cent. Furthermore, the yield of the soluble, non-diffusible products markedly decreases, and the products become very dark; these results amplify earlier observations⁴.

In Series B, increasing amounts of lysine hydrochloride were added to reactants in which the amount of aspartic acid was progressively reduced. (For each quantity of aspartic acid deleted, a molar equivalent of lysine was added.) In the products of this series, the proportion of aspartic acid drops to 23 per cent; the percentage of glutamic acid again increases, but the sum of the two is decreased by 27 per cent. This drop is accompanied by an increase in the proportion of lysine. The intensity of the colour of the products in Series B decreases somewhat; however, as in Series A, the yield of the product greatly decreases, thus off-setting the advantages gained by using lysine hydrochloride in the reactants.

The reactants in Series C were similar to those in Series B except that lysine was used in the form of the free base instead of the hydrochloride. The yield of the product, instead of decreasing as in the previous series, increases somewhat as the proportion of aspartic acid in the reactants is lowered, and the intensity of the colour of the product substantially drops. The proportion of aspartic acid in the products decreases to less than 10 per cent; although the percentage of glutamic acid again increases,

the sum of the two dicarboxylic amino-acids is 50 per cent or less in three cases. The content of lysine again increases. The relatively high value for neutral amino-acids noted for polymer C-4 is probably atypical; the value obtained with a similar polymer of another (untabulated) series was 15 per cent. Results with other series of polymers similar to A, B and C, however, have given comparable results in terms of yield, intensity of colour and amino-acid com-

Although the amount of glutamic acid in the reactants of the first three series was not varied, the proportion of this amino acid in the products increased regularly as the amount of aspartic acid present decreased. These results provide further evidence (compare ref. 1) that the thermal polymerization of amino-acids is internally directed in a non-random manner.

The reactants in Series D contained relatively large proportions of neutral amino-acids, in addition to appropriate quantities of dicarboxylic amino-acids and lysine free base. The proportions of neutral amino-acids in the products are about twice as large as those found in Series Band C. Within the series, the content of neutral aminoacids in the product increases slightly as their proportion in the reactants is increased; concomitantly, the percentage of dicarboxylic amino-acids decreases slightly. intensities are low and uniform, and yields, although somewhat lower than in Series C, are uniform. Comparable series of polymers, in which increasing proportions of basic and neutral (instead of only neutral) amino-acids were used, gave similar results, except that the yields decreased progressively. In these series, as in Series D, the products obtained contain about a third each of neutral, acidic and basic amino-acids. (Independent of this work, Waehneldt and Fox have obtained proteinoids that contain about 60 mole per cent neutral amino-acids¹².)

The polymers tested were optically active, although the magnitude of the optical rotation was small compared with that of proteins¹³. These specific rotations are similar to those observed for acid-type proteinoids7; thermal polymers of lysine have shown little or no optical activity14. Some of the proteinoids were tested for catalytic action for decarboxylating oxalo-acetic acid. Unlike thermal polymers consisting predominantly or solely of residues of lysine 14,15, the present polymers exhibited little or no catalytic activity.

The percentages of each polymer eluting from a 'Bio-Gel P-4' column in the same volume required for bovine albumin were 12, 16, 22, 32, 36 and 34, respectively, for the polymers C-1 to C-5. This increase parallels the increase in lysine content, an observation that is consistent with the earlier finding⁵ that proteinoids rich in lysine are of greater molecular weight than are acid proteinoids.

This investigation has shown that the addition of lysine free base to reactants comprised predominantly of dicarboxylic amino-acids leads to thermal condensation products of which the contents of aspartic acid can be easily controlled without adversely affecting either the yield or appearance of the product. In the presence of a sufficient proportion of neutral amino-acids and lysine free base, products are obtained which contain about a third each of basic, dicarboxylic and neutral amino-acids. These proportions of amino-acids, which are intermediate between those of acid and lysine-type proteinoids. resemble more closely the composition of proteins than earlier described for thermal polyamino-acids. Such polymers thus may be more suitable for use as models of biogenic and of abiogenic proteins.

I thank Mary Horner for technical assistance. C. A. Ponnamperuma, P. X. Callahan and K. R. Skrettingland for use of the amino-acid analysers, and M. R. Heinrich and S. W. Fox for review of the manuscript. This work was presented in part at the 152nd meeting of the American Chemical Society, New York, September, 1966.

The Thymus and the Precursors of Antigen Reactive Cells

by J. F. A. P. MILLER G. F. MITCHELL

The Walter and Eliza Hall Institute of Medical Research, Melbourne, Victoria

The thymus is important in providing an adequate pool of immunologically competent cells. Thymectomy does not reduce the number of precursor cells, but removes the influence necessary for their differentiation into antigen reactive cells.

THE bone marrow is a source of primitive stem cells which are characterized by their capacity for extensive proliferation, self renewal and differentiation into a variety of more mature cells. The colony forming unit is a stem cell which gives rise, in irradiated hosts, to large clones of erythroid and myeloid cells1. In both irradiated and non-irradiated animals there is a steady stream of cells

from the bone marrow to the thymus and to secondary lymphoid tissues, such as the lymph nodes and spleen. There are thus, in the bone marrow, cell types capable of repopulating the lymphoid compartment of the thymus and the pool of immunologically competent cells²⁻⁴. It is not clear whether there are separate stem cells for the myeloid tissues, the thymus and the immuno-competent, cell pool, although recent work suggests that the colony forming unit may also function as a lymphoid stem cell⁵.

The thymus plays an important part in building up an adequate pool of immunologically competent cells. When thymectomy is performed before this pool has been built up, for example, at birth, the number of cells in it is markedly less than normal and an impairment of those immunological reactions known to be mediated by these cells is immediately evident^{6,7}. When thymectomy is performed in adult life, or after an adequate pool has been built up, no immunological defects become evident until months later⁸⁻¹⁰, presumably after the pool has been depleted as a consequence of the limited life span of some of its cells and the immunological commitment of others. If, however, mice which have been thymectomized in adult life are subjected to total body irradiation, the anatomical and functional regeneration of the immune system is impaired¹¹⁻¹³. The exact relationship between the thymus, the pool of immuno-competent cells and precursors of them is unknown. Very few lymphocytes within the thymus can be detected as antigen-reactive cells¹⁴ and very few cells can be shown to have emigrated from the intact thymus¹⁵. It is unlikely that the thymus exerts an effect on the population of immuno-competent cells once they have been produced, for antigen-reactive cells respond to antigen by differentiation and proliferation to antibody-producing cells as efficiently in the normal as in the thymectomized animal⁶⁻⁷. Neonatal thymectomy thus does not inhibit the response of antigen-reactive cells to antigen and must therefore impair the production of antigen-reactive cells from some more immature, antigenindependent, precursor cells.

We report here the results of a time course study on the appearance of antigen-reactive cells in normal and thymectomized irradiated mice injected with bone marrow cells, thymus cells or both. Antigen-reactive cells are detected by their ability, when injected into heavily irradiated mice together with sheep erythrocytes¹⁴, to produce discrete clusters of haemolysin-producing cells in the spleen¹⁴. In this system, antigen-reactive cells are assumed to be the immediate precursors of antibody-producing cells and to belong to the same cell lineage. They are defined as cells which react to antigen, not by the production of detectable amounts of antibody, but by undergoing proliferation and differentiation to give rise to a line of antibody-producing cells.

Precursors of antigen-reactive cells are detected by incubating, in irradiated hosts and for varying periods of time, cell populations which lack antigen-reactive cells (such as bone marrow or thymus) in the absence of the relevant antigen. At the end of the incubation period, the spleen and thoracic duct lymphocyte pool of the irradiated recipients are assayed for their content of antigen-reactive cells. Mice of the highly inbred CBA strain were used in all experiments. Thymectomy of neonatal or adult mice was performed as described earlier16. Bone marrow cells were obtained from the femurs and tibiae of 2 month old normal mice and 2 month old clinically healthy mice thymectomized at birth, and were injected intravenously into 2-3 month old recipient mice of the same strain. Neither thymus cells nor sheep erythrocytes were injected into the irradiated hosts in the first experiment reported here. Some of the recipient mice had been thymectomized when 6 weeks old and all had been subjected to 900 rads of total body irradiation 4 h before marrow injection. They were killed at weekly intervals and the number of cells in their spleens capable of reacting to sheep erythrocytes was determined by the haemolytic focus assay technique of Kennedy et al.14.

As Fig. 1 shows, bone marrow from either normal or neonatally thymectomized donors contains precursors which, after a period of incubation of between 1 and 2 weeks in irradiated hosts, have developed into sheep erythrocyte-reactive cells. After between 3 and 4 weeks, the numbers of such cells produced in the spleens of the

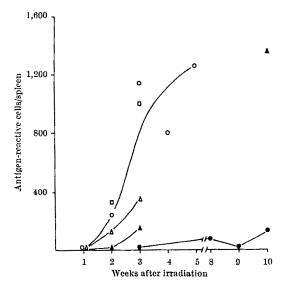

Fig. 1. Number of antigen-reactive cells detected at weekly intervals in the spleens of heavily irradiated CBA mice injected with bone marrow cells: \bigcirc , mice injected with 10° to 10° bone marrow cells from normal donors; \triangle , mice injected with 10° bone marrow cells from normal donors; \bigcirc , mice injected with 10° bone marrow cells from normal donors; \bigcirc , mice injected with 10° to 10° bone marrow cells from normal donors; \bigcirc , mice injected with 10° to 10° bone marrow cells from normal donors; \bigcirc to 10° bone marrow cells from normal donors. Each point represents the average value of five to forty determinations.

non-thymectomized irradiated mice inoculated with 106 or 107 bone marrow cells have reached the levels found in normal mice, that is, 1,000-2,000 (refs. 6 and 7). In contrast, the number of antigen-reactive cells detected in the spleens of adult thymectomized irradiated hosts never exceeded 200, even as late as 10 weeks after irradiation. The irradiated mice injected with marrow had their thoracic duct cannulated 2-9 weeks after irradiation using a method modified from that of Boak and Woodruff¹⁷, and the number of circulating lymphocytes and antigenreactive cells was determined as described previously4. Figure 2 shows that the number of cells recoverable in 48 h in sham-thymectomized irradiated mice increased from less than 10 million 2 weeks after irradiation to 40 million 7 weeks later. By contrast, no significant increase in the size of the 48 h pool was recorded from 2 to 9 weeks after irradiation and marrow protection in adult thymectomized mice. The total number of antigenreactive cells in the 48 h mobilizable pool increased between 4 and 9 weeks after irradiation from 120 to 1,000 in the sham-thymectomized irradiated controls but only from 15 to 66 in the thymectomized irradiated mice The number of antigen-reactive cells per million thoracic duct lymphocytes was virtually the same in mice of both groups 4 weeks after irradiation and then increased significantly only in the controls. By 9 weeks after irradiation the thymectomized irradiated mice, in comparison with controls, showed not only an absolute deficiency of antigen-reactive cells but also a reduced proportion of such cells per million lymphocytes. similar deficiency has been reported before in neonatally thymectomized mice4.

All these data clearly indicate that the precursor cells, which are antigen-independent and derived from marrow, differentiate and proliferate into antigen-reactive cells

Table 1. Number of sheep-erythrocyte-antigen-reactive cells in the 48 h mobile lymphocyte pool of sham-thymectomized and thymectomized, marrow protected, irradiated mice

Group	Weeks after irradiation	reactive cells/	no. of antigen- reactive cells/ 48 h mobilizable pool
Sham-thymectomized	4	5	120
irradiated	9	25	1,000
Thymectomized	4	3	15
irradiated	9	6	66

largely under the influence of the thymus. Precursor cells of marrow origin cannot, on their own and in the absence of the host thymus, differentiate into antigenreactive cells. Furthermore, it is evident that the neonatally thymectomized mouse does not lack precursor cells but simply lacks the influence necessary to drive these cells along the path leading to the production of antigen-reactive cells. Two questions are immediately evident: what is the nature of this thymus influence and why is there a lag period of about one week before antigenreactive cells become detectable?

The simplest relationship between the thymus and the pool of antigen-reactive cells would be one in which lymphoid precursor cells of marrow origin are transformed in the thymus to lymphocytes, some of which migrate out and mature further to become antigen-reactive cells. If this is true, the one week lag period already noted could be explained by the failure of bone marrow cells to repopulate the thymus of irradiated hosts during the first week after irradiation¹⁸. Furthermore, antigen-reactive cells ought to be detected in populations of thymus lymphocytes incubated for prolonged periods of time in irradiated hosts. Accordingly, experiments were set up to check these possibilities. One hundred million marrow cells or 100 million thymus cells were given by slow intravenous injection to two sets of irradiated mice, and spleen cells from these were transferred after one week into two further sets of irradiated mice. Cell suspensions from the spleens were passaged serially at weekly intervals into further irradiated recipients, one spleen equivalent being passaged each time. The controls received no initial inoculum and only irradiated spleen was serially transferred. At each passage, aliquots of the cells pooled from the spleens of one set of mice were assayed for their content of antigen-reactive cells by the haemolytic focus assay method14. There was no histological evidence of thymus lymphocyte repopulation in irradiated mice killed at weekly intervals in this experiment. It can be seen from Fig. 3 that incubation of the original thymus cell suspension in successive generations of irradiated hosts for up to 3 weeks yielded no more than fifty antigenreactive cells. Similarly, incubation of the original bone marrow cell suspension for a total period of 3 weeks gave values not significantly different from those obtained when only irradiated spleen was passaged. This last result is in contrast to that obtained when the bone

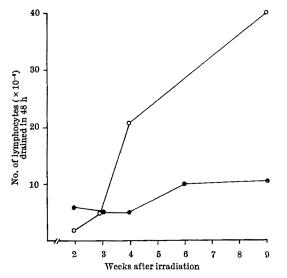

Fig. 2. Total number of lymphocytes drained in 48 h from the thoracic duct of adult *CBA* mice cannulated at intervals from 2 to 9 weeks after sham-thymectomy (\bigcirc) or thymectomy (\bigcirc) at 2 months of age, 900 rads and injection of 10° syngenet marrow cells. Each point represents the average of determinations made on three to four mice.

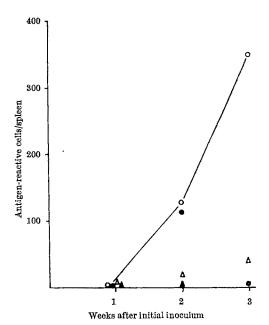

Fig. 3. Number of antigen-reactive cells detected in the spleens of heavily irradiated mice after the injection of bone marrow or thymus cells. ○, Number detected in mice receiving one initial inoculum of 10³ bone marrow cells from normal adult donors (from Fig. 1); ♠, in mice incubating for only 1 week spleen cells transferred at weekly intervals from successive sets of irradiated mice initially inoculated with 10³ bone marrow cells; △, in mice incubating for only 1 week spleen cells transferred at weekly intervals from successive sets of irradiated mice initially inoculated with 10³ thymus cells; ♠, in mice incubating for only 1 week spleen cells transferred at weekly intervals from successive sets of irradiated mice initially inoculated with 10³ thymus cells; ♠, in mice incubating for only 1 week spleen cells transferred at weekly intervals from successive sets of irradiated mice not initially inoculated. Each point represents the average of five to ten determinations.

marrow inoculum was incubated for 3 weeks in a single irradiated host. It can be argued that, because the original suspension is diluted at each transfer, the number of marrow cells incubated for the entire period of time must be less than 10⁸. But, even if a ten-fold dilution at each passage is assumed, so that only the equivalent of 10⁵ cells was incubated for 3 weeks, at least 350 antigenreactive cells would be expected in each spleen in the final host (Fig. 1).

These results, taken at their face value, suggest that the thymus lymphocyte population lacks cells capable, on their own, of giving rise to cells producing haemolysin, even after 3 weeks in successive generations of irradiated hosts. This does not support the hypothesis that bone marrow precursors become antigen-reactive cells only after differentiating within the thymus. The failure of bone marrow precursors to become antigen-reactive cells in the absence of thymus repopulation (Fig. 3) does, however, suggest the possibility that thymus lymphocytes might be essential for the rapid differentiation of precursors derived from marrow into haemolysin-producing cells. Experiments were therefore set up in which either 108 thymus cells or 108 bone marrow cells were incubated with or without sheep erythrocytes for one week in heavily irradiated hosts; cells from the spleens of these mice were transferred to a second group of irradiated mice together with either sheep erythrocytes only or with 107 bone marrow cells and sheep erythrocytes. The capacity of the second host to produce haemolysin-plaque-forming cells was assayed 4, 6 and 8 days after transfer according to the technique of Jerne¹⁸. Figure 4 shows the results obtained when spleens were transferred from thymusincubating donors and Fig. 5 shows results obtained when spleens from bone marrow incubators or uninoculated donors were transferred. It is evident that a significant plaque forming cell response occurred within 6 days in mice which received bone marrow cells, sheep erythrocytes and spleen transferred from those irradiated donors inoculated with thymus cells and sheep erythrocytes one week

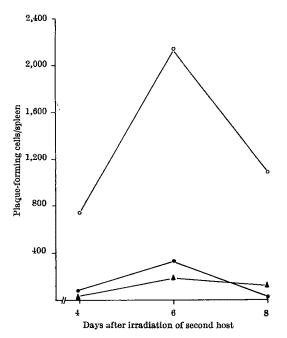

Fig. 4. Production of haemolysin-plaque-forming cells in the spleens of heavily irradiated mice (second hosts) injected with cells (sheep erythrocytes (SRBC) and/or bone marrow cells (BM)) and spleen transferred from a first irradiated host injected with thymus cells (T) and/or SRBC.

Each point represents the average of three to twelve determinations.

before. There was no significant response if thymus cells were incubated without sheep erythrocytes in the first irradiated host, and a similar result was obtained if bone marrow cells were not given to the second irradiated host. We do not think that the response in the latter host can be ascribed to the transfer of lymphocytes of the type found in the circulating pool contaminating the thymus cell population and stimulated by the antigen given to the first host. If this had been so, one could have expected, in the second host, a response which was not dependent on the simultaneous presence of bone marrow cells.

Our results corroborate those obtained by Claman et al.20, who showed that suspensions containing a mixture of adult marrow and thymus cells were far more active in producing haemolysins against sheep erythrocytes when transferred to irradiated syngeneic recipients than could be accounted for by summating the activities of each cell population alone. They also show that the thymus lymphocyte population has had to react with antigen in some way before interaction with bone marrow cells could be expected to result in significant haemolysin production. The nature of the reaction between thymus cells and antigen is obscure, but it is presumably the same as that which has been observed when cells derived from a thymus graft responded vigorously to antigenic stimulation by mitosis^{21,22}, a response which did not, by itself, lead to antibody production23.

All the experimental evidence thus indicates that there is some sort of interaction between thymus cells, bone marrow cells and antigen. Two alternative interpretations of the results will be offered here. One possibility is that antigen-reactive cells are derived from the thymus but fail to react to sheep erythrocytes by producing plaque

forming cells in heavily irradiated hosts, because of the destruction or disruption of an essential mechanism for trapping antigens. It has been shown that the splenic follicles and marginal zone cells play a part in trapping antigens²⁴, and that they are destroyed by irradiation²⁵ and rapidly reconstituted by cells derived from bone marrow¹⁸. In these experiments, cells reactive to sheep erythrocytes could be derived directly from some of the thymus lymphocytes, the bone marrow population providing cells essential for the repair of the antigen trapping apparatus.

Our failure to detect precursors of antigen-reactive cells in populations of thymus lymphocytes would suggest an alternative interpretation; that the precursors of the haemolysin-producing cells are derived from marrow. The thymus might then provide cells necessary for trapping antigen or, on the other hand, thymus cells may be essential for the rapid differentiation of marrow precursor cells into antigen-reactive cells. It is difficult, however, to envisage the mechanism of action of these thymus cells.

In summary, sheep erythrocyte-antigen-reactive cells are the progeny of antigen-independent precursor cells, the differentiation of which is dependent on the thymus. The thymectomized animal does not lack precursor cells but lacks the influence necessary for their differentiation into antigen-reactive cells. Such reactive cells have not been detected after the incubation of thymus lymphocytes for up to 3 weeks in irradiated hosts. When, however, marrow cells were introduced, haemolytic, plaque forming cells appeared within a week in response to a challenge of sheep erythrocytes. One interpretation of these results is that the thymus does indeed provide antigen-reactive cells but that these cannot be detected in irradiated hosts

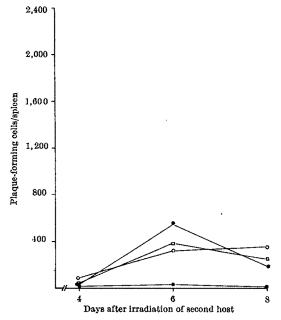

Fig. 5. Production of haemolysin-plaque-forming cells in the spleens of heavily irradiated mice (second hosts) injected with cells (sheep erythrocytes (SRBC) and/or bone marrow cells (BM)) and spleen transferred from a first irradiated host injected with BM and/or SRBC.

unless marrow cells are made available presumably to repair an essential antigen-trapping apparatus disrupted by the irradiation. Another interpretation is that thymus lymphocytes lack antigen-reactive cells or their precursors but act to provide a stimulus to ensure the rapid differentiation of precursor cells derived from marrow.

We thank Sue Hughes and Winnie House for excellent technical assistance. This work was supported by grants from the National Health and Medical Research Council, the Australian Research Grants Committee, the Damon Runyon Memorial Fund for Cancer Research, Inc., the Jane Coffin Childs Memorial Fund for Medical Research and the Anna Fuller Fund.

Note added in proof (November 6, 1967). Since this paper was submitted, we have demonstrated that the precursors of the haemolysin forming cells are derived not from either the thymus or thoracic duct lymphocytes but from bone marrow²⁶.

Coventry and Warwickshire Hospital, Coventry

P. J. GAFFNEY, jun. R. W. CARRELL H. LEHMANN

MRC Abnormal Haemoglobin Research Unit. Department of Biochemistry, University of Cambridge

The forty-second amino-acid of the β-chain of human haemoglobin and its equivalent in all known globins (CDI) is phenylalanine; it stabilizes the haem by direct contact. In Haemoglobin Hammersmith, replacement by serine causes instability of the molecule and thereby severe haemolytic Heinz body anaemia.

A HEAT precipitable haemoglobin fraction has been reported in a female child suffering from a congenital anaemia who was studied for several years at the Royal Postgraduate Medical School, Hammersmith^{1,2}. recently, an unrelated infant suffering from an apparently identical disorder was observed in Coventry. Both patients have a severe haemolytic anaemia unrelieved by splenectomy and red cells containing large inclusion bodies This article summarizes studies on (Heinz bodies). the haemoglobin of these patients. In both cases, it was established first that the precipitable haemoglobin did not separate from haemoglobin A on electrophoresis at alkaline pH, and that there were no peptide chains carrying charges different from those of normal α and β chains of haemoglobin A $(\alpha_2 \beta_2)$ when the haemoglobin of either patient was submitted to starch gel electro-phoresis in 6 molar urea³. The haemoglobin was precipitated by adding one part each of 0.1 molar phosphate buffer, pH 7.4, and 0.01 molar zinc chloride to one part of 10 per cent haemoglobin solution. The washed precipitate was dissolved in 0.1 normal hydrochloric acid and precipitated with acetone4, and fingerprints and peptide analysis were carried out as described before. This procedure showed that the position of the tryptic peptide (βTpV), which comprises residues 41-59 of the 146 aminoacid residues of the \beta-chain, had changed. Some fingerprints showed only one peptide with the electrophoretic mobility of βTpV but with a much lower chromatographic (vertical) mobility (Fig. 1). Other fingerprints (Fig. 2)

showed three peptides with the electrophoretic mobility of βTpV and βTpV oxidized (ox). "Ox" indicates that the methionine in position β55 has been oxidized to methionine sulphoxide during the handling of the haemoglobin The three peptides were in the position of specimen. β TpV, β TpV ox and the third was below β TpV ox at about the same distance below the peptide at which βTpV ox is found below βTpV . A positive staining reaction for methionine was given by the uppermost peptide in the position of βTpV , and also by that in the position of βTpV ox, whereas in the case of haemoglobin A the peptide in this position does not stain for methionine. The lowest peptide did not give this reaction.

These findings were interpreted as indicating an aminoacid abnormality of \$TpV which involves a decrease in the hydrophobic properties of this peptide. The upper peptide which gave a faint reaction only for methionine and also for ninhydrin would represent the normal BTpV and arise from some coprecipitation of normal haemoglobin; the principal peptide in the middle would be the new \$TpV, and the lowest peptide would be its oxidized

The principal abnormal peptide was purified by successive paper electrophoresis and chromatography. To prevent contamination by normal \$TpV ox, which would be found in the same area of the fingerprint, the isolated vertical BTpV strip obtained after electrophoresis was exposed to hydrogen peroxide vapour for 6 h. This treatment converts methionine into methionine sulphoxide6

Fig. 1. Fingerprint (peptide chromatogram) of a nearly pure haemoglobin Hammersmith obtained by zinc precipitation. The upper arrow indicates the area where the β TpV is found in haemoglobin Å. The lower arrow indicates where β TpV is found in haemoglobin Hammersmith.

and confers on the principal abnormal peptide the chromatographic mobility of the lowest of the three peptides discussed here, thus freeing it from any possible contamination with normal \$TpV ox.

One-third of the purified peptide obtained from paper was hydrolysed with 6 normal hydrochloric acid for 42 h in a sealed evacuated tube. A control sample of the The prolonged normal peptide was treated similarly. hydrolysis time was used throughout this work, in view of the resistance to acid hydrolysis of the β41-42 Phe-Phe bond. The results of amino-acid analysis are given in Table 1, where it will be seen that the abnormal peptide differs from $\beta ATpV$ by an extra serine residue and the loss of one residue of phenylalanine. Such a replacement of a hydrophobic residue by a polar residue explains the decreased chromatographic mobility of the abnormal peptide.

Table 1. Amino-acid composition of normal and abnormal $\beta {\rm TpV}$ and chymotryptic peptides β 41–45

Chymotryptic peptides 41-45 βTpV Normal Abnormal No. of residues of: Normal Abnormal Amino-acid Aspartic acid Threonine Serine Glutamic acid 1.0 3.0 1.2 1.9 2·1 1·0 Proline Glycine Alanine Valine Methionine 0.8 1.1 2.0 Leucine Phenylalanine Lysine Yield/residue 3.0 2.0 0.9 0.020 0·9 0·043 0.030 0.023

As Table 2 shows, βTpV contains three residues of phenylalanine7. To determine which phenylalanine had been replaced, the remaining two-thirds of the purified abnormal peptide were digested with chymotrypsin for 4 h. The double rules in Table 2 indicate where chymotryptic cleavage would be expected, and the arrows indicate where most important splitting occurred. Figure 3 shows a fingerprint of the chymotryptic digest—a similar digest of the normal \beta TpV was prepared at the same time and a

fingerprint was also prepared. The dotted line in Fig. 3 shows the area where a peptide was found in the fingerprint of the normal digest but not in that of the digest of the abnormal \$TpV, and below a peptide is found which is absent in the digest of the normal peptide. This is the only difference between the two digests. Table 1 shows the analysis of these two chymotryptic peptides. In the case of the control, the amino-acid composition corresponds to βA 41-45, that is, Phe, Phe, Glu, Ser, Phe, but the abnormal peptide has the composition Phe, Ser, Glu, Ser, The substitution is provisionally placed in the second position, as the ninhydrin colour in the abnormal peptide was blue whereas an N terminal serine would cause the ninhydrin stain to be brown, and the presence of the C terminal phenylalanine was indicated by a chymotryptic cleavage at β 45.

This deduced sequence was confirmed by dansylation of the chymotryptic peptide according to Gray and Hartley and Smellie and Hartleys, By this means it could be demonstrated that the N terminal sequence of the abnormal tryptic peptide BV and of the abnormal chymotryptic peptide β 41-45 was Phe-Ser. The formula of the haemoglobin Hammersmith can thus be written α₂β₂ 42 Phe-→Ser or in the helical notation β CD1 Phe-→ Ser.

To determine the proportion of the abnormal haemoglobin in the whole haemolysate a fingerprint was prepared after oxidation of the globin with hydrogen peroxide vapour. The oxidized normal and abnormal BV peptides were eluted, their amino-acids were analysed and the yields of each peptide were compared. In addition, the total BTpV from the whole haemolysate was analysed after electrophoresis followed by gel filtration ('Sephadex G-25') to remove any contaminants from paper. proportions from the integrated values of serine were compared with other residues in the combined peptide. The result obtained from these two experiments showed that the abnormal haemoglobin amounted to 30 per cent of the total. This proportion of haemoglobin Hammersmith in the haemolysate underestimates the original amount of the abnormal fraction, because part of it would have been made unavailable in the form of Heinz bodies.

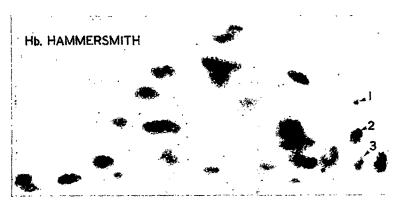

Fig. 2. Fingerprint (peptide chromatogram) of partially purified haemoglobin Hammersmith. (1) Normal β TpV staining positive for methionine. (2) Abnormal β TpV staining positive for methionine. This peptide is found in the position of normal β TpV oxidized, which would not yield a positive methionine reaction. (3) A small amount of abnormal β TpV oxidized.

When Grimes et al.2 labelled reticulocytes with radioactive leucine, almost 50 per cent of the newly formed haemoglobin was heat precipitable.

The abnormality in haemoglobin Hammersmith is of the same type as that observed in haemoglobin Köln β FG4 Val \rightarrow Met¹⁰, Genova β B10 Leu \rightarrow Pro⁴ and Sydney β Ell Val→Ala¹¹. When haemoglobin Sydney was described the repeated findings in unstable haemoglobins of amino-acid substitutions not involving a change of charge were suggested to be in a definite pattern. An internal hydrophobic residue the hydrophobic bonding of which contributes to the stability of the molecule is replaced by another of different dimensions and thereby the stability of the molecule is decreased. A replacement at such a site by a charged residue would presumably not be compatible with the survival of the tertiary structure¹². In the case of haemoglobin Genova when the leucine of a helix is replaced by a proline which cannot enter the helical sequence, and in another unstable haemoglobin, haemoglobin Freiburg¹³ where a residue is deleted in the B helix (β B5 Val), the distortion of the molecule which occurs must be sufficient to explain the instability of the molecule. In haemoglobins Köln and Sydney the residues which are replaced form hydrophobic (van der Waals) bonds with the haem. The phenylalanine β CD1 which is replaced in haemoglobin Hammersmith is an invariant residue which is present in all haemoglobins and myo-

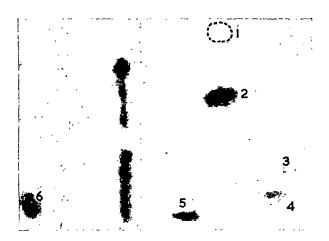

Fig. 3. Fingerprint (peptide chromatogram) of the chymotryptic digest of the abnormal \$T{\rm pV}. (1) Area where \$\beta\$ 41-45 is found in the fingerprint of the chymotryptic digest of normal \$T{\rm pV}. Amino-acid analysis indicated the composition of the other peptide as (2) \$\beta\$ 41-45 of haemoglobin Hammersmith. (3) 41-55; (4) 48-55; (5) 41-59; (6) 56-59.

globins. In a model it can be seen to lie closely to the porphyrin of the haem and in planar relation to it. It can therefore form strong van der Waals bonding with the haem and must be an important stabilizing force within the molecule. Its replacement by the non-charged but polar serine residue should cause a more severe instability than the Val-Met and Val-Ala replacements of haemoglobins Köln and Sydney respectively. This would agree with the greater clinical severity of haemoglobin Hammersmith haemoglobinopathy.

It is interesting that in both instances of this condition we have been unable to demonstrate the abnormal hacmoglobin in either parent—whereas haemoglobins Köln, Genova and Sydney are patently familial. We conclude that the chance of a child affected with haemoglobin Hammersmith surviving and producing children has been (and still is) slight, and its observation is therefore likely to be limited to patients in whom it has arisen as a new mutation.

The amino-acid substitution described here represents the first observation in human haemoglobin involving phenylalanine. The messenger RNA codons for phenylalanine are uracil-uracil-cytosine (UUC) and UUU, and two of the codons for serine are UCC and UCU14. single mutation in the second base from U to C in either of the two phenylalanine codons can therefore be responsible for the Phe→Ser substitution in haemoglobin Hammersmith. This is in agreement with the general pattern according to which human haemoglobin variants can be considered to have arisen from single point mutations¹⁵.

One of us (R. W. C.) was supported by a grant from the Wellcome Trust and was on study leave from Christchurch Hospital, New Zealand.

Attachment of Rapidly Labelled RNA to Polysomes in the Absence of Ribosomal RNA Synthesis during Normal Cell Differentiation

bу

J. B. GURDON
Department of Zoology,
University of Oxford

P. J. FORD

Department of Experimental Biology, National Institute for Medical Research, Mill Hill, London Anucleotate mutant tadpoles of Xenopus laevis synthesize rapidly-labelled RNA but no detectable ribosomal RNA or ribosomes. Experiments demonstrate that high molecular weight RNA synthesized by these mutants attaches to polysomes active in protein synthesis.

In animal cells the synthesis of rapidly labelled RNA in the nucleus and the subsequent appearance of such RNA in cytoplasmic polysomes usually take place at the same time as the synthesis of ribosomal RNA and cytoplasmic ribosomes. This and other relationships¹⁻³ have suggested that the synthesis of messenger RNA, its transport to the cytoplasm and its incorporation into polysomes may be dependent on, or in some way linked to, the synthesis of ribosomal RNA and ribosomes. This possibility can be tested most directly in conditions in which rapidly labelled RNA is synthesized but ribosomal RNA is not. There seem to be only two natural conditions in which these two kinds of synthesis are clearly separated. The first is during cleavage in frogs4, sea urchins5 and other animals. Only very small amounts of non-transfer RNA are synthesized during the early cleavage stages of embryos, however, and at this stage of development most ribosomes seem to exist as monomers; it is therefore difficult to demonstrate the attachment of rapidly labelled RNA to polysomes during cleavage in embryos. Nevertheless RNA synthesized by a sample of sea urchin embryos, mostly in early cleavage stages, becomes associated with polysomes which may not, however, be active in protein synthesis. The second condition in which the synthesis of rapidly labelled RNA and ribosomal RNA are clearly separated is during the life of Xenopus embryos and tadpoles, homozygous for the anucleolate mutation7 which prevents the synthesis of any ribosomal RNA⁸. Purified ribosomes from the anucleolate mutant contain very small amounts of labelled non-transfer RNA9, and it has not yet been demonstrated that any of the high molecular weight RNA synthesized by these mutants becomes associated with a population of polysomes active in protein synthesis. The experiments described here provide such a demonstration, and therefore show that the attachment of rapidly labelled RNA to polysomes is not necessarily dependent on or linked to ribosomal RNA synthesis during cell differentiation.

Polysomes in Xenopus Embryos

We have used the following criteria for the identification of polysomes: sedimentation properties before and after release from cytoplasmic membranes; behaviour after ribonuclease treatment; and activity in protein synthesis. These features have been demonstrated on the same sample of tadpoles derived from one mating. After hatching (stage 38 of Nieuwkoop and Faber¹o), sixty tadpoles were microinjected with a mixture of ¹⁴C-aminoacids (Radiochemical Centre, Amersham). This was prepared by adding ¹⁴C-leucine at 305 mc./mmole to mixed ¹⁴C-amino-acids lacking methionine and histidine; the mixture was freeze dried and taken up in modified

Barth's solution¹¹. After 15-25 min, these embryos and an excess of unlabelled embryos of the same age were washed several times and homogenized together in 3 ml. of 0.25 molar sucrose, made up in TKM buffer (35 mmolar tris hydrochloric acid at pH 7.4, 50 mmolar potassium chloride and 1 mmolar magnesium chloride), using ten strokes of a loose fitting glass ball homogenizer. homogenate was layered over 1 ml. of 1 molar sucrose-TKM and centrifuged at $13,000g_{\text{max}}$ for 15 min at 0° C (MSE 3×5 ml., swing-out rotor at 12,000 r.p.m.) to remove nuclei, pigment, etc. The supernatant was carefully withdrawn as far as the interphase and divided into three equal parts. One part was treated with 0.5 per cent 'Triton X-100' (Lennig Chemicals) for 0.5 h at 0° C, another was treated with ribonuclease at 1 $\mu g/ml$. and 'Triton' at 0.5 per cent for 0.5 h at 0° C, and the last remained untreated for 0.5 h at 0° C. Each part was layered on top of an 18 ml. 10-30 per cent linear sucrose-TKM gradient lying over a 1 ml. cushion of 60 per cent sucrose-TKM. After centrifugation at 0° C for 2.5 h at $90,000g_{\text{max}}$ (MSE 3×20 ml., swing-out rotor at 25,000 r.p.m.), fractions were collected, and their optical density read at 240, 260, 280 and 320 m μ . Each fraction was then precipitated onto Whatman GF 83 filters by addition of 50 per cent TCA and counted in a liquid scintillation counter. The results are shown graphically in Fig. 1a-c. The optical density profiles have been corrected for scattering by reference to absorption at 320 mu. From tube 5 onwards the optical density at 260 mu is largely the result of nucleic acid as judged by the 280: 260: 240 my. ratio. In all cases (Fig. 1a-c), monosomes have sedimented as far as tube 7. In the untreated sample (Fig. 1a), components containing RNA have sedimented faster than the monosomes and some have accumulated on the dense cushion at tube 23. These fast sedimenting components show substantial incorporation of ¹⁴C-amino-acids into a product which is insoluble in acid; they are therefore active in protein synthesis. 'Triton', like deoxycholate, releases polysomes from fragments of cytoplasmic membrane, and treatment with it has caused the RNA-containing particles which previously reached the 60 per cent sucrose cushion, to sediment more slowly, reaching tubes 10-15 where there is an increase in $E_{260\,\mathrm{m}\mu}$ (Fig. 1b). This would be expected of polysomes released from cytoplasmic membranes. Finally, Fig. 1c shows that treatment with low temperature ribonuclease causes these fast sedimenting components to sediment with monosomes, the optical density and ¹⁴C-radioactivity of which is proportionately increased (Table 1)—a result expected of polysomes but not of RNA attached to non-ribosomal components¹². All criteria that we have used indicate that the RNA-containing components, which sediment faster than single ribosomes, behave as polysomes active in protein synthesis.

Attachment of Rapidly Labelled RNA to Polysomes

Because tadpoles which are homozygous for the anucleolate mutation (0-nu) die before feeding, they must be obtained by crossing two 1-nu frogs, heterozygous for the mutation. Among the progeny of such a cross 88 0-nu tadpoles were identified individually by phase-contrast microscopy of excised tail tips¹¹. At the hatching stage (stage 37/38, ref. 10), each 0-nu tadpole was microinjected with about 30 mul. of 3H-uridine solution, that is 3H-uridine labelled primarily in the 5C position at 30 c./mmole (Radiochemical Centre, Amersham), and made up to 8 mc./ml. of modified Barth's solution. 3-4 h later, the injected 0-nu tadpoles were washed and homogenized together with the unlabelled and 14C-amino-acid labelled tadpoles described. The labelled and unlabelled tadpoles together numbered 450 and were all obtained from the The tadpoles labelled with same $1-nu \times 1-nu$ mating. The tadpoles labelled with ${}^{3}\text{H-uridine}$ were part of the sample analysed on the 10-30 per cent sucrose gradients described. 3H-radioactivity was counted at the same time as 14C-radioactivity in each sample using a three channel liquid scintillation counter. The channels ratio method was used to calculate the efficiency of counting (15 per cent for tritium and 50 per cent for carbon-14) and the proportion of counts present in the 3H-channel resulting from carbon-14 radioactivity. In tadpoles labelled for no more than 3-4 h, only 2-3 per cent of the radioactivity introduced with ³H-uridine enters DNA and the rest enters RNA¹³. ³Hradioactivity is plotted in Fig. 1a and b, and it is seen that labelled RNA is present in the polysome region of these gradients, whether treated with 'Triton' or not. Light ribonuclease treatment removes virtually all ³H-radioactivity from the polysome region (Fig. 1c. Table 1). In another experiment in which 0-nu embryos were labelled with 3H-uridine for 18 instead of 3.5 h, we also found heterogeneous RNA associated with poly-

We conclude from these experiments that non-ribosomal RNA synthesized by 0-nu tadpoles becomes associated with cytoplasmic components which behave like polysomes. A small amount of transfer RNA, which is synthesized as usual by 0-nu tadpoles^{8,9}, would be expected to become attached to polysomes, and the

Table 1. Distribution of 3 H-labelled rna and 14 C-labelled protein, and of total unlabelled rna (E_{280} m μ), in different regions of the gradients shown in Fig. 1a–c

The regions of each gradient are defined by tube number. The recovery in each region is expressed as a percentage of total recovery (last column).

following experiment was therefore carried out to determine whether this was the only kind of RNA to become attached to polysomes in our experiments. From among the progeny of a second $1-nu \times 1-nu$ mating, fifty 0-nutadpoles were identified individually as described earlier. At stage 37/38 they were microinjected with the 3H-uridine preparation used before. After 3.5 h they were washed and combined with 130 unlabelled 1-nu and 2-nu tadpoles of a similar age. After homogenization in 0.25 molar sucrose-TKM, and centrifugation at 13,000g for 15 min as described before, the supernatant (3.0 ml.) was placed on top of a stepped gradient of 0.8 ml. of 1 molar sucrose-TKM and 0.8 ml. of 2 molar sucrose-TKM¹². fugation at 0° C for 2.5 h at 176,000 $g_{\rm max}$ (MSE 3×5 ml. swing-out rotor at 40,000 r.p.m.) yielded a pellet which contained 20-30 per cent of the total 260 mµ optical density added to the tube, and which must therefore have contained, as was intended, most of the components which previously sedimented faster than the monosomes. pellet was dissolved in 1 ml. of 0.01 molar sodium acetate at pH 5.0, 1 mmolar versene, 50 mmolar sodium chloride, 4 μg/ml. polyvinyl sulphate, and 0.5 per cent sodium dodecyl sulphate, a solution intended to dissociate protein from RNA without causing degradation of RNA. Purified ribosomes from 150 unlabelled tadpoles were added at this point to provide an appropriate amount of optical density at 260 mu in the ribosomal RNA region of the next sedimentation gradient. The RNA solution, from which sodium dodecyl sulphate had been removed, was layered

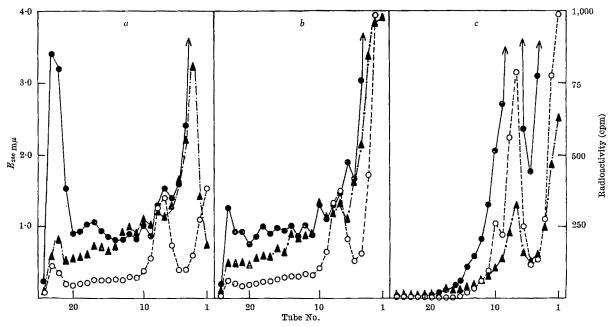

Fig. 1. Distribution of optical density at 260 mμ (O --- O), ¹⁴C-protein (•--- Φ), and ²H-RNA (▲-···· ▲) among the fractions of sucrose gradients. The labelled protein and RNA were attached to, or part of, ribosomes or polysomes. The embryos were labelled and the supernatant samples prepared for each gradient as described in the text. The three samples of embryos supernatant were incubated in sucrose-TKM medium supplemented in the following ways before being layered over the sucrose gradients: (a) no addition; (b) 0.5 per cent "Triton X-100"; (c) 0.5 per cent "Triton X-100" and I μg/ml. ribonuclease.

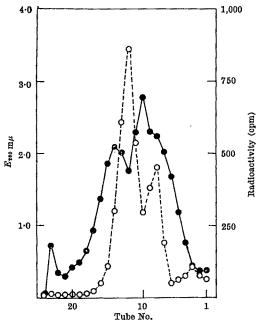

Fig. 2. Distribution of optical density at 260 m μ (\bigcirc - - - \bigcirc) and *H-RNA (\bigcirc — \bigcirc) among the fractions of a sucrose gradient. Embryos were labelled and the BNA extracted as described in the text.

on top of a linear gradient of 5-20 per cent sucrose containing sodium acetate, versene, polyvinyl sulphate and sodium chloride, as described earlier. After centrifugation at 5° C for 14 h at 75,000 g_{max} (MSE 3×20 ml., swing-out rotor at 23,000 r.p.m.), fractions were collected from the gradient and assayed for optical density and radioactivity as before. The result (Fig. 2) shows that the labelled RNA extracted from polysomes sedimented throughout the gradient with a peak of radioactivity lying between the typical optical density peaks of 28S and 18S ribosomal RNA. A similar sedimentation profile has been described previously for the total DNA-like RNA extracted from 0-nu embryos labelled for 3 h⁹. We conclude from this experiment that very little of the rapidly labelled RNA which is synthesized by 0-nu tadpoles and which becomes attached to polysomes is transfer RNA.

Interpretation of Results

We consider our results show that rapidly labelled RNA can become associated with polysomes in the total absence of ribosomal RNA synthesis. We discuss here some of the more obvious kinds of error which if not excluded would seriously affect the interpretation of our results. It is essential that our preparation of 0-nu tadpoles should not have been contaminated by any wild-type or heterozygous tadpoles, and that they should have been in a normal lifelike condition during the experiment. In this connexion, we wish to stress that each 0-nu tadpole was identified individually by a procedure which has previously been shown to be very reliable when tested for ribosomal RNA synthesis by sucrose gradient analysis. Furthermore, any contamination of our sample of 0-nu tadpoles by ones capable of synthesizing ribosomal RNA would have been clearly revealed as peaks of 28S and 18S radioactivity in Fig. 2. The 0-nu tadpoles used for these experiments were between stages 37 and 39 and were not morphologically distinguishable from wild-type tadpoles. They seemed entirely normal when homogenized at stage 39. Our principal conclusion is based on results obtained with 0-nu tadpoles from two different matings.

The possibility that we were dealing with aggregates of ribosomes or with RNA-containing cell components other than polysomes seems very unlikely, for ribo-nuclease converted the fast-sedimenting components into monosomes. Contamination of our polysome preparation by nuclear components containing RNA seems unlikely, not only because of the ribonuclease effect just mentioned but also because nuclei and other components were discarded after the initial centrifugation into a pellet at 13,000g for 15 min. Evidence that this effectively separated nuclear from cytoplasmic components is provided by the finding that the supernatant of this first centrifugation contained 95 per cent of the 14C-protein radioactivity, but less than 50 per cent of the ³H-RNA radioactivity originally present in the homogenate. We used a loose fitting ball-type homogenizer known to provide a high yield of unbroken tadpole nuclei14.

Bacterial contamination was excluded by removal of all unhatched embryos from jelly and membranes, the use of streptomycin sulphate and benzylpenicillin at 0.01 µg/ml. in all incubation media, and by extensive washing before homogenization. These precautions have been found to eliminate bacterial contaminations, and the presence of any labelled bacterial RNA in our samples would have been seen as 23S and 17S peaks of 3H-radio-

activity in Fig. 2.

In summary, our results permit the following conclu-First, they show that rapidly labelled RNA of anucleolate amphibian embryos becomes associated in a few hours with cytoplasmic components which have all the biochemical properties expected of polysomes. Because this takes place in anucleolate tadpoles, that is 3-4 days after ribosomal RNA was last synthesized, the synthesis, transport and attachment of rapidly labelled RNA to polysomes cannot be linked in any way to ribosomal RNA synthesis. A similar conclusion has been drawn from short-term experiments with HeLa cells treated with puromycin15 or infected with vaccinia virus16, but does not seem to have been reached previously for normal differentiating cells in natural conditions, or in circumstances in which ribosomal RNA synthesis is so clearly dissociated from the synthesis of other kinds of RNA. While our results demonstrate that the synthesis and translation of rapidly labelled RNA (presumably messenger RNA) are quite independent of ribosomal RNA synthesis, they do not exclude the possibility that mRNA attachment to polysomes is linked to the transport and assembly of ribosome subunits released from degraded ribosomes. As a second conclusion, our results provide direct evidence that newly synthesized non-transfer and non-ribosomal RNA can become attached to a population of polysomes, some of which are active in protein synthesis and the component ribosomes of which were synthesized 3-4 days before, during oogenesis. While this might have been expected in view of the substantial amount of DNA-like RNA synthesized by anucleolate embryos, it does not seem to have been demonstrated before.

We thank Drs J. R. Tata and C. F. Graham for their comments on the manuscript, and the Medical Research Council for support.

LETTERS TO THE EDITOR

ASTRONOMY

Arguments for the Presence of Undiscovered Satellites

In this communication we summarize the results of recent work leading to the prediction of the presence of three new satellites, one each for Jupiter, Saturn and Uranus, and specify those properties of the satellites and their orbits which can be deduced.

In the course of a rediscussion of the characteristics of the satellite systems of the principal planets we showed the following. (a) With the exception of the Galilean satellites of Jupiter, commensurability relations of the type

$$\sum N_i n_i = 0$$
 (1)

(where n_i is the mean orbital angular rate of the *i*th satellite of a planet, N_j is an integer or zero, and the summation is over all satellites) probably arise by chance and have no physical significance. (b) Simple resonance perturbation of particles in Saturn's ring does not explain the observed positions of gaps or relative minima; this conclusion has also been reached by Alfvén¹. (c) The eight inner satellites of Saturn, including the recently discovered Janus², obey the following rule

$$n_i + n_{i+2} = (1 + m_i k) (n_{i+1} + n_{i+3})$$
 (2)

where n_i is defined as in equation (1), m_i is a small positive integer, k a constant = 0·1505439, and that such a rule will certainly not arise by chance. (d) Similar equations can be formed for the satellite system of Uranus if an extra satellite is postulated in an orbit between the present inner pair, Miranda and Ariel. (e) Two solutions pertain to the Jovian system, both of which postulate an extra satellite between Amalthea and Io, with values of k=0.365514, n=432.189 deg/day or k=0.262087, n=417.802 deg/day.

We note that, to quite a high degree of exactness, the constant k_q (subscript q denoting the satellite system) is proportional to the mean density, ρ_q , of the corresponding primary. The second of these postulated Jovian satellites fits accurately into this scheme. The relation between k_q and ρ_q (in egs units) may be expressed as

$$k_q = (0.180 \pm 0.008) \rho_q + (0.026 \pm 0.022)$$
 (3)

To investigate the possibility that an extension of equation (2) might serve to portray the detailed structure of Saturn's ring, we calculated $n_{0,i}$ given by

$$n_{0,i} + n_2 = (n_1 + n_3) (1 + 0.1505439m_i)$$
 (4)

where n_1 , n_2 , n_3 are the angular rates of Janus, Mimas and Enceladus, respectively, and m_i a positive integer. It is inferred that these $n_{0,i}$ represent stable orbits, and hence maxima in the particle density in Saturn's ring; and for $m_i \leq 10$ this is found to be the case. We find that $n_{0,i}$ must be rejected because its value of 473.288 deg/day is less than that of n_i which is 480.667 deg/day, and that $n_{0,2}$ lies outside the ring with the value 585.23 deg/day. We note, however, that this latter value might represent an undiscovered satellite outside the Roche limit, provided its mean density exceeds 1.3 g cm⁻³. hypothesis receives support from Alfvén's proposal that the Cassini division and the relative minimum in the ring at 876.2 deg/day are the cosmogonic shadows of Mimas and Janus, respectively, caused by these satellites sweeping up part of the plasma which later condenses into ring grains, the semi-major axes of whose orbits are 0.65 those of the plasma particles. Alfvén defines the "fall-down ratio" as the ratio between the present semi-major axis of the sweeping satellite's orbit and the radial distance from the centre of the primary to the corresponding ring gap.

The ratios for the pairs (Mimas-Cassini division) and (Janus-876·2 deg/day gap) are $1\cdot541$ and $1\cdot492$, respectively. We find that the other major gap, the Lyot gap separating rings B and C and centred on $1,117\cdot8$ deg/day, would be the cosmogonic shadow of our proposed satellite, with a fall-down ratio of $1\cdot539$ agreeing very well with the ratio for Mimas. The photometric profile of the Lyot gap is at present uncertain, but it seems likely that the proposed satellite has a mass intermediate between those of Mimas and Janus (hence probably a magnitude at mean opposition of about 13), and orbital eccentricity similar to that of Mimas (0·02).

Some elements for the conjectured satellites are summarized in Table 1.

Table 1. PARAMETERS OF THE CONJECTURED SATELLITES OF JUPITER, SATURN AND URANUS

Primary	Conjectured satellite orbital angular rate (deg/day)	Period	Mean distance from primary (equatorial planetary radii)	kq	64
Jupiter	417·802 432·189	0d 20h 40m 47s 0d 19h 59m 24s		0·262087 0·365514	1.334 1.334
Saturn Uranus	585·23 214·558	0d 14h 45m 03s 1d 16h 16m 08s	2.31	0·1505439 0·316532	0.684 1.60

We thank Dr A. Dollfus for providing his latest photometric data on Saturn's ring, and for useful discussion. This work was supported by the Science Research Council and by the US Air Force.

PLANETARY SCIENCE

Theoretical Model for the Chandler Wobble

EULER is generally credited with having been the first to show that an axially symmetric rigid body, with a fractional difference between the equatorial and polar moments of inertia equal to that of the Earth, could undergo a free nutation with a period of about 300 days. That is, in a body-fixed co-ordinate system, the instantaneous axis of rotation would describe a cone about the polar axis with a 300 day period. It could have been expected that such a motion, even if present primordially, would have been damped almost completely by natural dissipative processes within the Earth. Such a motion would show itself in a periodic variation in astronomic latitude of a given site on the Earth's surface, because the rotation axis moves only slightly with respect to an inertial frame1. Despite the expectance of almost complete damping, repeated attempts were made in the nineteenth century to uncover indications of a variation in latitude with a 10 month period. None was definitely established, but in 1891 Chandler² announced a variation with a period of 428 days, about 40 per cent larger than predicted. Newcomb soon realized that the period of free nutation for the Earth would be greater than the rigid-body value, because of the fluid nature of the oceans and elastic yielding of the solid earth, and he proposed that Chandler's observations were indeed of the free nutation3. Systematic observations of latitude variations have been made since the turn of the century and clearly indicate the presence of an oscillation with this 14 month period (see Fig. 1). The amplitude of this oscillation has a maximum of about 0.3 sec of arc, that is the inclination of the instantaneous axis of rotation to the figure axis does not seem ever to exceed about 0.3 sec of arc.

What prevented this free nutation from being completely damped? Many suggestions of mechanisms to excite the Chandler wobble have been put forward during the past 75 yr, but none has proved satisfactory. question is still considered by most geophysicists to be largely unanswered. The purpose of this communication is to describe a new, and admittedly speculative, model that we conceived independently. The idea is based on Fig. 1 which, although extending over too short a time interval to be definitive, seems to have an envelope characteristic of "beat" phenomena. We therefore propose that these latitude variations do indeed exhibit beats, attributable to an interaction between core and We speculatively assume that the core has sufficient rigidity to have a free nutation frequency nearly equal to the corresponding frequency of the mantle alone. These separate frequencies, modified by coupling, can be expected to be present in the Chandler motion. The data (Fig. 1) suggest a beat period of about 40 yr. Results of theoretical calculations, although quite sensitive to the assumed rigidity and difference in equatorial and polar moments of inertia of the core, indicate that such a period is reasonable for our proposed model. (Of course, if the model proves adequate, the observed beat period can be used to infer these properties of the core.)

We suppose that this resonant oscillation is excited asynchronously, through a non-linear interaction, by the differential luni-solar torques exerted on the core and mantle. Using a suitably parameterized model, we are investigating numerically the possible motions of this complicated, three degrees of freedom, dynamical system. Apart from the well known expressions for the luni-solar gravitational torques, the model includes a restoring torque (inertial coupling term), which is proportional to the separation of the figure axes of core and mantle, and a viscous torque which is a non-linear function of the difference in angular velocity of the coupled parts. In first approximation both core and mantle are considered rigid. The transfer of the required energy between core and mantle seems possible on the basis of preliminary calculations. Quantitative results, to be reported in a subsequent communication, will include the relations between the model parameters and the amplitudes and frequencies of the Chandler motion.

How may this model be checked experimentally? The supposition that a beat frequency is present in the Chandler motion can, of course, be tested conclusively by awaiting future measurements. In fact, data have

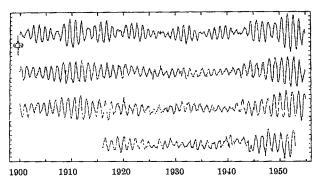

Fig. 1. Variations of the two orthogonal components of the position of the Earth's rotation axis with respect to the axis of figure (from ref. 1). The top two curves show the unsmoothed observations for one component, before (first curve) and after (second) removal of the seasonal variation. The last two curves, in reversed order, show similar variations for the second component. The first three curves were obtained by the International Latitude Service, the last with the Photographic Zenith Tube at Washington.

accumulated for 12 yr since Fig. 1 was compiled and would be expected to exhibit a decreasing amplitude in the oscillation. Although the nineteenth century observations may not be very reliable, we intend to re-examine the best of these and, after separating the annual term¹, seek evidence bearing on the predicted amplitude modulation of the Chandler term.

The presence of two important frequency components in the Chandler motion is, of course, also consistent with the apparent breadth of the power spectrum of the polar motion in the vicinity of 0.8 cycles/yr¹. In the past, the corresponding decrease in the amplitude of the autocorrelation of the Chandler data—approximately 10 per cent for a 14 month lag—was interpreted as indicating a damping time of approximately a decade and led to suggestions that the free nutation was being excited by random impulses¹. In our model, the amplitude of the auto-correlation will also decrease, as observed, but after longer intervals will rise again, the period being equal to that of the beat frequency. Furthermore, the problem of the anomalously small Q value for the Earth, inferred from the "damping" of the Chandler motion, is automatically disposed of.

If this model of the Chandler webble proves fruitful, it might be interesting to consider the more complicated case of a non-axially symmetric mantle which may be appropriate for Venus or the Moon.

Sinking Rates of Radioactive Fallout Particles in the North East Pacific Ocean, 1961-62

THE resumption of nuclear weapon testing in the atmosphere in September 1961 provided an opportunity to investigate the sinking rate of radioactive fallout particles in the North East Pacific Ocean. The stopping of weapon testing in the atmosphere between November 1958 and September 1, 1961, gave sufficient time for radionuclides with relatively short half-lives which were released by tests before 1958 to decay. Weapon testing began in the Soviet Union on September 1, 1961, and by November 4, 1961, at least fifty nuclear devices had been detonated in the atmosphere, including fifteen megaton or multimegaton devices1. In the North East Pacific Ocean, the beginning of the 1961 test series coincided closely with the beginning of the winter storms and their heavy rainfall. This provided a mechanism for quickly depositing the fallout nuclides, rainfall being the principal mechanism for removing such particles from the atmosphere². Radioactive fallout material from these tests was detected in marine samples in mid-September 1961.

The gamma-ray activity was analysed in samples of sediment collected in July and August 1961 and in the summer of 1962. No activity caused by the presence of radionuclides from fallout was detected in thirty-nine samples collected in 1961 (general area sampled shown in Fig. 1), while twelve samples collected in June 1962 from

this area contained detectable amounts of several radionuclides from fallout.

Special sediment samples were collected in August and September 1962 for analysis of their gamma-ray activity. These samples were collected by siphoning off the muddy water above the interface between water and sediment in open gravity cores. I assume that the sediment particles suspended in the water were resuspended during the coring and retrieval operations and that this sediment was the most recently deposited material.

The muddy water recovered was transferred to a plastic container in which it was dried under infrared lamps aboard ship without washing or further handling, to minimize contamination. When the samples were dry the containers were sealed and wrapped in plastic which was changed just before analysing the gamma radiation. Depending on the amount of sediment recovered, the gamma radiation was analysed for 100-1,000 min using a 3×3 in. $(7.6 \times 7.6$ cm) sodium iodide (thallium) crystal connected to a photomultiplier and a multichannel analyser. The gamma-ray spectra obtained were analysed using a computer programme which estimated the abundance of eight radionuclides (potassium-40, cobalt-60, zinc-65, zirconium-95-niobium-95, ruthenium-103-106, bismuth-214, chromium-51, cerium-141) and estimated the 95 per cent confidence interval based on counting statistics3. The sample was considered to have no significant activity if the calculated activity was equal to or less than the estimated 95 per cent confidence interval.

Of the various radionuclides from fallout detected, the pair zirconium-95-niobium-95 was selected as the best for this study because of its relative short half-life (65 days), its abundance in fallout² and its known association with particles in sea water⁴. The apparent absence of zirconium-95-niobium-95 in sediments collected in July and August 1961, just before the resumption of testing.

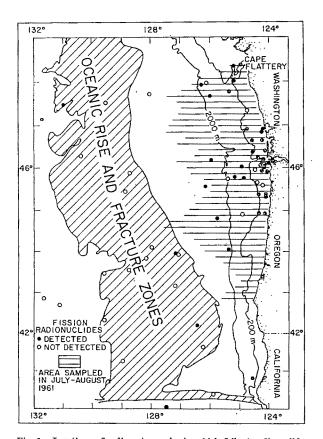

Fig. 1. Locations of sediment samples in which fallout radionuclides were detected (●) and not detected (○) in 1962. Sediment samples collected in July and August 1961 (area shown by horizontal rules) near the continent had no detectable quantities of radionuclides from fallout.

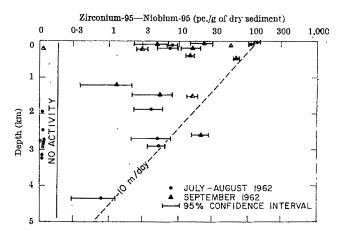

Fig. 2. Observed abundance of zirconium-95—niobium-95 in specially collected sediment samples taken in August-September 1962 from various depths in the region shown in Fig. 1. The dashed line indicates the expected decrease in zirconium-95—niobium-95 activity with depth assuming a constant supply of radioactive particles sinking at a rate of 10 m/day with no dilution by non-radioactive sediment after deposition or during sampling operations.

and its presence in shallow water deposits nearly everywhere in 1962 provides convincing evidence that the radioactivity detected was caused not by fallout derived from earlier weapons tested nor by the misidentification of the gamma-ray spectra of radionuclides occurring naturally in these sediments, but by fallout particles deposited after September 1961.

In the locations nearest the continent, the radioactive particles could have been transported and deposited either by processes near the ocean floor, or by sinking through the overlying sea water or by both. Thus the data for sample locations near the continent provide little information about sinking rates of the radioactive particles.

The deepest localities are apparently shielded from the accumulation of sediment by transport along the bottom of the ocean by the irregular bottom topography associated with the oceanic rise and fracture zones (Fig. 1). Thus the presence and abundance of fallout radionuclides in the sediment from these areas provide information about the sinking rates of the radioactive particles.

If we assume that the first radioactive fallout arrived in the area immediately after the testing began (September 1, 1961), the radioactive particles must have settled about 13 m/day to have reached a depth of 4.4 km (Fig. 2) by the time the sample was collected on August 8, 1962. Even if we discard the data for the deepest station because of possible contamination (for which there is no evidence) we must still assume sinking rates of at least 9 m/day to account for the radioactivity from fallout detected in three samples from depths between 2.6 and 2.9 km (Fig. 2). In short, it seems that the radioactive particles sank at rates near 10 m/day to account for the presence of zirconium-95—niobium-95 (half-life 65 days) in the sediment at these depths.

It is also interesting to note that the observed decrease in activity of zirconium-95-niobium-95 (Fig. 2) with depth corresponds rather closely to the expected decrease resulting from a steady state injection of fallout with the particles sinking at a rate of 10 m/day. This apparent relationship may be entirely fortuitous because it would demand not only a quasi steady state input of fallout particles, which seems scarcely likely, but also an absence of appreciable dilution of the recently deposited fallout particles by non-radioactive sediment during deposition and during the coring operations.

I have no data on the grain size, composition or density of these radioactive particles although fallout from other weapon tests has been studied^{1,2,5,6}. It is possible to calculate the probable grain size of the radioactive particles, having sinking rates of 10–13 m/day, by assum-

ing that the particles are spherical, have a density of 2.5 g/cm³ (typical of fused silicate glass), and obey Stokes law during gravitational settling through sea water $(S=35~{\rm p.p.t.},~T=5^{\circ}~{\rm C})$. Such a calculation shows that a sinking rate of 10 m/day corresponds to grains 16μ in diameter, and 13 m/day corresponds to grains 18µ in diameter.

These calculated grain sizes are consistent with the known behaviour of fallout particles where grains less than about 20μ in diameter tend to be transported primarily by atmospheric motions^{1,2}. Such grains could easily have been transported long distances from the test sites in the USSR and widely dispersed in the surface layers of the North East Pacific Ocean.

No doubt smaller particles also fell into the ocean surface layers, but my data do not provide any information about possible size distribution in the fallout. Not only do the larger particles sink more rapidly but they also have greater activities than the smaller particles because the activity of fallout particles is proportional to the volume of the particle. Thus the larger particles probably contributed the bulk of the radionuclides from fallout in these sediments when collected in 1962.

I thank A. H. Seymour, C. A. Barnes, D. A. McManus, D. E. Engstrom and the captain and crew of the R.V. Brown Bear for their assistance. This work was supported by the US Atomic Energy Commission and the US Office of Naval Research.

Lake Levels and Quaternary Climates in the Eastern Rift Valley of Kenya

For more than 20 yr, the accepted sequence of pluvial and interpluvial climatic fluctuations during the late Pleistocene and Holocene in East Africa has been based on the evidence of high level shorelines and lake sediments in the Nakuru-Elmenteita basin in the Eastern Rift Valley, Kenya. The nomenclature was formally established in 19471 and 19482 but it had been published several years earlier. The sequence of lake level variations was originally studied by Leakey^{3,4}. The pluvial (high lake level) phases shown in Table 1 were suggested, separated by dry interpluvials during which the lakes were lower. It was believed that these phases could be recognized in evidence from lake shorelines, sediment sections and river terraces in other parts of Africa.

Recently there has been strong criticism of the use of essentially climatic units as stratigraphical units and as

Table 1

Oldest)

the basis of geological correlation between parts of Africa. This is expressed in the volume published as the result of the symposium on the systematic investigation of the African later Tertiary and Quaternary held at Burg Wartenstein under the auspices of the Wenner-Gren Foundation in July 1965, which was attended by many scientists of great experience in the field study of African Quaternary stratigraphy⁵. They recommended that an internationally approved code of stratigraphical nomenclature be accepted for the African later Tertiary and Quaternary which should "make clear the distinction between rock units, time-stratigraphic units, biostratigraphic units, and other units" (page 890). This distinction has not always been made up to now; for example, the term "Gamblian" has been used to mean: (a) certain strata at the type site (Gamble's Cave, marked GC on the map) and elsewhere in the Nakuru basin; (b) the pluvial period during which these strata were laid down; and (c) rocks in other areas believed to have been laid down during the same pluvial period. Such a nomenclature is likely to give rise to confusion and unsound correlations. advantages of climate as the basis of a stratigraphical classification were well summarized earlier by Flint (ref. 6, page 279).

There has also been some re-examination of the geological evidence for the earlier pluvial periods in East Africa (Kageran, Kamasian, Kanjeran) the existence of which was accepted with that of the later phases at the congresses of geology and prehistory held in the 1940s and early 1950s^{1,2,7}. It has been suggested that the geological evidence for the earlier pluvial phases, even in the type areas, is not always convincing^{6,9}. The evidence in the Nakuru-Elmenteita basin for the Gamblian, Makalian and Nakuran sequence of lake level fluctuations, however, has not been re-examined in detail since the 1930s and is

still generally accepted.

My recent work on the shorelines and sediments of the Nakuru-Elmenteita basin (1965-67) suggests that the use of the terms Gamblian, Makalian and Nakuran to indicate pluvial climatic units may also be open to doubt. concentrated on tracing the shorelines of the former lakes, looking for the few lake-shore cliffs which can be found and for coastal and shallow-water sediments such as pebbles and sections of sands and diatomaceous silts. I then measured their altitude as accurately and precisely as possible, using a Zeiss self-aligning level ('Koni 025'). In the early part of the work, for the levelling of the most important features such as the Menengai shoreline, Gamble's Cave and the Bahati plain, I levelled both ways, to and from the control points, to check the accuracy of the work, and found it to be quite satisfactory in every In the later work there was not sufficient time to level both ways, but I believe the results of this levelling are also reliable. Results in some cases did not agree with those of earlier workers3,4,10,11; I think this is because of the better apparatus that I used and above all because of the better height information, maps and air photographs which were available. The levelling in the 1920s was based on the railway height control points which are in many ways not satisfactory; I was able to use the Survey of Kenya network of trigonometrical stations and bench marks which have since been established in the area. On the map, the contours drawn with a solid line are taken from the recent 1:50,000 maps and give quite a good picture of the basin. They are unfortunately not drawn on these maps of the south of the basin and the form lines shown there with broken lines are taken from maps drawn in the early part of the century and give only

a rough indication of the topography.

I found (a) that the "Gamblian" phase is represented by a single shoreline slightly above 6,370 ft. (circa 600 ft. above Lake Nakuru) which may be linked to the lowest overflow from the basin which is at about 6,390 ft. The overflow is at the point OF on the Bahati plain (see map). The lake level seems to have been stabilized for some time

⁽Most recent) Nakuran post-pluvial wet phase—Lake Nakuru circa 145 ft. above present Makalian post-pluvial wet phase-Lake Nakuru circa 375 ft. above present

at the height of this outlet from the basin and the shoreline is thus not strictly an indication of a lake stillstand at a "pluvial maximum" climatic peak. It could reasonably be called the "Gamblian shoreline" if by this one means the shoreline contemporary with the beach sand found by Leakey in Gamble's Cave. The Gamble's Cave sand is at 6,344 ft. (Survey of Kenya datum) which is very close to the altitude of similar sand and pebble sections at the north end of the basin below the 6,370 ft. Menengai shoreline (3/6 at 6,343 ft., 1/7a at 6,341 ft.). The shoreline is best developed between points 1/7a and P on the map; it is untilted or at most very slightly tilted. I found (b) that the evidence for the "Makalian" shoreline, which according to Leakey included features at 373-379 ft. above Lake Nakuru, seems from my levelling to be spread over a height range of about 343-484 ft. above the lake, with no suggestion of a consistent tilt. Shoreline erosion and shallow water sedimentation seem to have taken place within these heights, but the evidence does not suggest a single important stillstand at about 375 ft. above the lake. (c) The lake stillstand of the "Nakuran" phase is based, according to the published accounts3,4, on only two shoreline features. One of these is a clear cliff line which according to my levelling is at 5,944 ft. (approximately 160 ft. above the lake); the other, reported as a "bank of stratified mud" (ref. 4, page 199), could not be found. (d) Evidence from the sediment sections, although not all were studied in detail, does not seem to demand an interpretation in terms of Gamblian, Makalian and Nakuran pluvial peaks; McCall studied recent lake sediments in this area and concluded that the three sediment divisions he recognized "appear to owe their existence primarily to factors other than climatic" (ref. 12, page 72).

It seems clear that there were considerably larger lakes (up to 600 ft. deep as opposed to the present depths of less than 10 ft.). in the Nakuru-Elmenteita basin during parts of Upper Pleistocene and Holocene times, and it is likely that these lakes resulted from wetter and possibly colder climatic conditions of which there is evidence from many other parts of Africa. There does not seem to be, however,

 $\langle :: \rangle \wedge$ NAKURU-ELMENTEITA BASIN MENENGAL Land above 6,600 feet 115 -6400- 6,400 feet contour Crater rim (BASIN EBURU

Fig. 1

sufficient evidence for the use of the terms Gamblian, Makalian and Nakuran to indicate climatic phases which may be correlated with possible pluvial or glacial phases from other parts of Africa and even Europe. Until absolute dates are obtained for material which can be linked to particular shoreline levels, any attempt at such correlations is of little practical value.

The first year of this research was financed by a Royal Society Leverhulme scholarship. I thank Dr W. W. Bishop and Mr A. T. Grove for advice and encouragement.

Fossil Manganese Nodules from Sicily

From the stratigraphically condensed limestones of the West Sicilian Jurassic, which overlie a white Trias-Lias reefoid facies. Wendt recorded fossil ferromanganese nodules1.

The shape of the fossil nodules varies from place to place and from bed to bed. Some occur as small, roughly spherical, crenulate bodies, showing well developed concentric structure, others are larger, mamillated, potato shaped masses, or the nodules may fuse into an irregular pavement. The nodules and crusts are, in fact, physically indistinguishable from their modern counterparts; and it is interesting that this same geo-graphical variation in nodule form is also found in modern examples². Recent manganese pavements have been reported from the Blake Plateau³.

The fossil nodules are also comparable with recent ones in exhibiting lamination, which may disappear inwards, and, in some cases, alternate light and dark bands1; at one locality, instead of the usual limestone or organic remnant, pieces of reworked volcanic tuff have formed the nodule nuclei, thus furthering the comparison⁵.

Preliminary microprobe analysis shows that the Sicilian nodules contain most of the trace elements which characterize modern examples; however, in the fossil forms, the quantity of iron is persistently greater than the manganese (compare Mero's analyses2). This is possibly a result of post-depositional migration of the more mobile manganese^{6,7}. Calcium also is high because of the accretion of the nodules in a former limestone environment.

Mineralogically, apart from calcite, only goethite and occasionally haematite are posi-

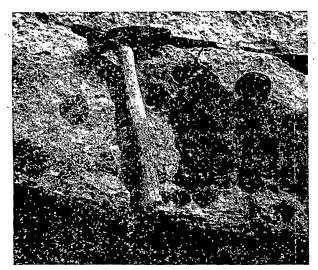

Fig. 1. Vertical section. Condensed bed with discrete, concentrically laminated ferromanganese nodules. Rocca Argenteria, Western Sicily. (Length of hammer handle, 36 cm.)

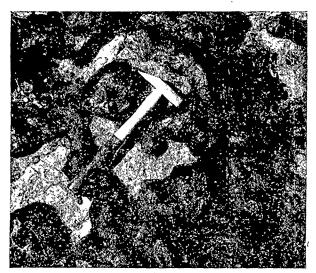

Fig. 2. Bedding surface. Condensed bed with fused ferromanganese nodules. Monte Kumeta, Western Sicily. (Length of hammer handle, 28 cm.)

tively identifiable by simple X-ray methods, the conclusion being that all the manganese oxides are colloidal or extremely fine grained—as is the case with many modern nodules². The fossil nodules described from the Cretaceous of Timor⁸, however, contain goethite with pyrolusite, hausmannite and probably cryptomelane.

The association of the fossil ferromanganese nodules with stratigraphically condensed beds is significant. Condensed beds must have been formed in an environment of minimal net sedimentation; in today's oceans the central deeps and current-swept topographic highs qualify as possible milieux, and it is in these two environments that ferromanganese nodules seem chiefly to occur now^{2,9,10}. The fossil nodules described by Molengraaf¹¹ from the East Indies occur in the presumed lithified equivalents of the red deep-sea clay; but there is little evidence for a deep-sea origin of the red condensed limestones of the Sicilian Jurassic. On the contrary, there is some evidence that these deposits were laid down in shallow water^{1,12}. Ferromanganese nodules themselves are no guide to depth; modern forms occur in a variety of shallow water environments13.

The condensed beds, in similar facies, encompass different time intervals from locality to locality (ref. 1 and personal communication from H. S. Torrens), showing that the conditions for their formation were not realized

solely during one period. The evidence therefore suggests that the condensed ferromanganiferous deposits from Sicily were laid down on transient topographic highs composed of the underlying Trias-Lias White Limestone, these topographic highs possibly being comparable with the non-magnetic seamounts now existing off the Iberian coast14.

PHYSICS

Electron Energy Distributions in Moving Striations

PEKAREK'S theory of the wave of stratification1 has recently been extended to cover self-excited moving striations2. This theory, which assumes a Maxwellian energy distribution, implies that an essential characteristic of moving striations is a phase shift between the maxima in the variation of the electron density and electron temperature. Time-resolved Langmuir probe and microwave measurements^{2,3} seem to verify the theory.

The theory is linear, however, whereas the large

amplitude and non-sinusoidal shape of the observed variations imply a non-linear wave. Comparison with the familiar stationary striations, which are often found in the molecular gases, would indicate the existence of a double peaked electron energy distribution4. The concept of electron temperature is then inadequate, particularly because the departure from Maxwellian form is greatest in the high energy tail of the distribution which determines the production rate of ions and metastables.

For this reason, the electron energy distribution in moving striations has been obtained using the Druyvesteyn probe technique. To achieve this, time-resolved first derivative measurements were made, the second derivative being obtained by graphical differentiation.

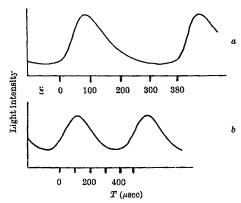

Fig. 1. Variation of light intensity. a, Discharge current 172 m.amp; b, discharge current 100 m.amp.

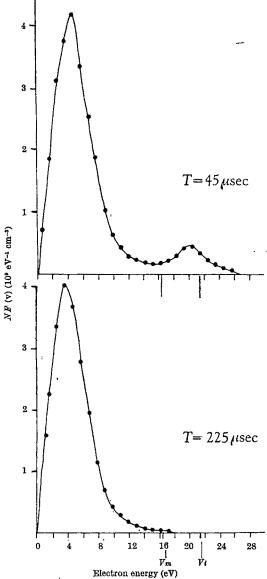

Fig. 2. Energy distributions in strictions with light intensity variation shown in Fig. 1a. Vm, Metastable potential (16.6 V); Vi, ionization potential (21.5 V).

The time-resolved first derivative characteristics were obtained by a sampling technique. A small sinusoidal signal was superimposed on the probe bias for a small part of each striation period and the fundamental frequency component of the probe current was measured. This quantity is proportional to the first derivative of the probe current-voltage characteristic. Measurements through a striation were made by varying the time delay of the signal pulse over a striation period. The fundamental component of the probe current resulting from the probe sheath capacitance is in quadrature to the component resulting from the first derivative and can be eliminated by phase sensitive detection. The arrangement for superimposing the a.c. signal on the probe bias was similar to that used by Boyd and Twiddy⁴. The d.c. bias was varied linearly by a motor and the output of the phase sensitive detector was taken to a chart recorder to give a continuous first derivative characteristic.

Measurements have been made in a hot-cathode discharge in neon (p=0.35 torr, 2R=5.6 cm, L=180 cm) in which two types of moving striation were observed, in both cases the phase velocity being directed from anode to cathode. The first type, present at discharge currents greater than 120 m.amp, had a frequency of 2.6 kc/s and a wavelength of 15.8 cm, corresponding to a phase velocity

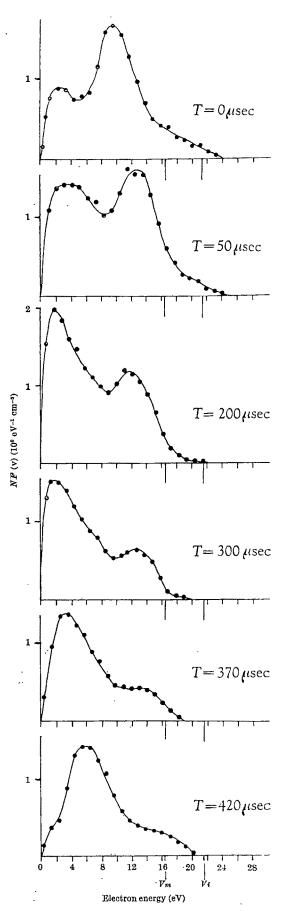

Fig. 3. Energy distributions in strictions with light intensity variation shown in Fig. 1b. Vm, Metastable potential (16-6 V); Vi, ionization potential (21-5 V).

of $4\cdot1\times10^4$ cm/sec. The dispersion relation for these striations was obtained by modulating the discharge current over a range of frequencies close to the natural frequency. The wavelength increased with frequency which showed these moving striations were backward waves. The group velocity was 3.9×10^4 cm/sec. The second type, present at a discharge current of 100 m amp, had a frequency of 2.1 ke/s and a wavelength of 8.5 cm, corresponding to a phase velocity of 1.8×10^4 cm/sec.

The spherical measuring probe was located 110 cm from the cathode and the a.c. signal applied to it had a frequency of 50 kc/s and a peak to peak amplitude of 0.5 V. This signal was applied for 12 usec in each striation period. The space potential was taken to be the point at which the first derivative was maximum.

Fig. 1 shows the observed variations of light intensity with time. Two energy distribution measurements made in the higher current striations are given in Fig. 2. The first measurement was made 30 µsec before the crest of the light intensity, the second 150 usec after the crest. These results show the two well defined groups of electrons which are characteristic of stationary striations, the higher energy group being produced by the acceleration of low energy electrons from the tail of the previous striation through a double space charge sheath4

Fig. 3 shows six measurements made in the striations occurring at the lower current. The first (T=0) was made 100 usec before the crest of the striation and the other distributions correspond to delays of 50, 200, 300, 370, 420 usec, respectively (striation period, 470 usec).

The second measurement (T=50) shows two groups of electrons, the high energy group, with mean energy of ~12 eV, having been produced by the acceleration of a low energy group through a potential step. The four subsequent measurements (T=200, 300, 370 and 420)show the depletion of this high energy group through the striation. Unlike the high energy electrons in the striations occurring at higher current this group is not completely exhausted but is accelerated through a further potential step to produce an energy distribution identical to that shown in the first measurement (T=0). A novel feature of this distribution is that the high energy tail, capable of direct ion-pair and metastable production, has been produced by the acceleration of electrons through two successive sheaths.

Linear Polymers in the Turbulence Vortices

Long chain linear polymers in dilute aqueous solutions show several anomalies, particularly a reduction in turbulent skin friction. Attempts have been made to explain such anomalies in terms of visco-elasticity. It is, however, worth considering the possibility that the effects arise from a "spiral combing" of the macromolecules in the cores of the vortices which constitute the turbulence. If aligned at an angle to a cylindrical surface of slippagewith their front ends in the faster flow on the interiorthese macromolecules would act as "sea anchors" bridging

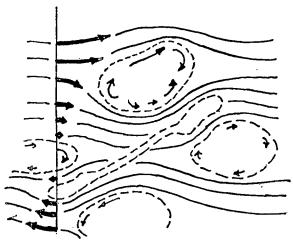

Fig. 1. Ends of a macromolecular tangle may get caught between other tangles.

the streamlines of different velocities, thereby increasing the effective local viscosity in these cores, and thus making these cores act more nearly as rigid bodies. In a plane shear flow such an alignment is improbable, for there a macromolecule, even if it happened to have been stretched, would tend to be turned by the vorticity of that flow until it is aligned with a streamline, and becomes free to slip with respect to other macromolecules so aligned. But the rather unusual circumstances necessary to produce such "combing" at a fairly large angle to the pathlines—namely, a brief spurt of a strong shear, followed by some reduction of the tendency of the fluid to sweep (turn) a stretched macromolecule towards a pathline—are indeed experienced by a macromolecule which is close to a vortex at the moment of its birth. As the diffusing vortex spreads over the macromolecule, this macromolecule first experiences a spurt of shear accompanied by the vorticity of an opposite sense; and by the time it is engulfed by the core (the vorticity of which would tend to sweep this macromolecule towards a pathline) the vorticity of the core is already diminished by the diffusion. It is therefore conceivable that an occasional macromolecule might be stretched by the spurt of the shear enough to have its end "caught" in the manner suggested in Fig. 1. Such "rigidized cores" would be less likely to diffuse, turn, stretch and break up than the vortices which constitute the turbulence in a homogeneous fluid; and so would more likely be formed in longer sections, and act as "rollers", namely, as more effective constituents of the vortex sheet formed by the turbulent layer. This explanation accounts also for other anomalies manifested by these solutions.

Musical Flames

Interaction between flames and sound was first reported by John Leconte in 1858 and has since been studied by Rijke, Rayleigh, Tyndall, Andrade¹ and many others. It was the subject of a special session at the fourth symposium of the Combustion Institute in 1952 under the heading "Oscillatory Combustion".

Leconte had noticed that a gas flame at a concert responded to certain beats of the music. Subsequent work attempted to analyse and explain this effect in terms of the properties of sound waves and those of flames². Because very characteristic changes in the shape of a flame can be produced by sound waves of specific frequencies, flames have been used as sound detectors in

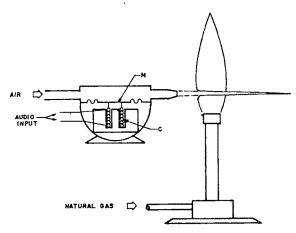

Fig. 1. The modulation of a bunsen burner flame by a jet of oxygen at right angles to the flame. The membrane, M, and the coil, C, are shown.

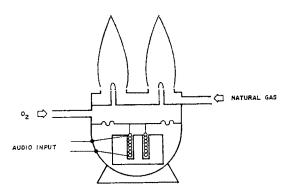

Fig. 2. A different arrangement of Fig. 1 using the acetylene and oxygen supply from a welding unit.

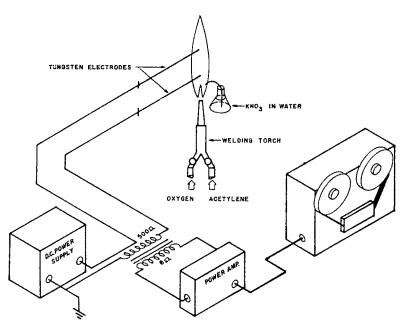

Fig. 3. Another method of modulating a flame using the output from the secondary winding of a transformer. Sufficient ionization is provided in the flame by a wick from a potassium nitrate solution.

acoustic research³. Experimenters have observed that the response of the flame is more energetic than the sound intensity which caused it; the flame thus acts as an amplifier, and feedback occurs⁴. Others have shown that flames can in fact accept and reproduce sound and music and act as loud-speakers, confirming the words attributed to Leconte² that we must "look upon all jets as musically inclined".

A very simple experiment (Fig. 1) uses a natural gas flame into which a jet of oxygen is blown at right angles. The flow of oxygen is modulated by motions of the membrane M, which in turn are imposed by the coil C (in practice a commercial loud-speaker membrane with its driving unit is easily adapted to form the flow modulation unit). Any electrical vibrations imposed on the coil membrane and oxygen flow will now be reproduced as audible sound by the flame. If these vibrations are taken from a tape recorder and constitute Beethoven's Fifth Symphony, a very fine rendering is obtained with a fidelity apparently limited only by the quality of the recording and the modulation unit. The "beats" which Leconte observed are clearly evident in the flame.

Many other arrangements are possible, of which we sketch only one (Fig. 2) conveniently operated from the acetylene and oxygen supply of a welding unit, with the same fine reproducing qualities.

In the experiments described, the modulation unit really produces the sound waves and the flame merely amplifies them, although the amplification, even on the laboratory scale described, is of the order of several hundred. We have found, however, that it is not necessary to modulate the flame physically; it can be done electrically as well, as was observed, on the shape of the flame and its wake only, by Zickendraht⁵. For this purpose a voltage is imposed on the flame between points near the base and near the end of the visible region. The voltage is taken from the secondary windings of a transformer, and it has to be biased to allow symmetrical oscillations. The desired input is fed to the primary transformer windings, and will be audibly reproduced by the flame. The experiment is sketched in Fig. 3. The acetylene and oxygen used do not contain sufficient ionizable species, but these are readily added by touching to the base of the flame an asbestos wick feeding an alkali salt like potassium nitrate in water solution. The arrangement shown will fill a

large room with music or speech.

The observations described show that the production of sound by the flame is associated with the surface in which the chemical energy is liberated, corroborating the concept of flame surface tension6. This is also the place where the strongest light emission takes place, and the latter also contains the imposed modulation. By optically forming an image of the light from this region of the flame in one of these experiments on a suitable photocell, amplifying its output and feeding it to a loud-speaker, the input from the tape recorder is again recovered in audible form. Using the experiments in Figs. 1 and 2 a delay will occur caused by the time the gas takes to flow from the modulation unit to the flame, but no delay is apparent with the experiment in Fig. 3.

The optical photocell arrangement can be used to show that even the weak flame of a candle has the properties described. If one talks at a candle flame, the monitoring photocell will reproduce the voice, albeit volume and fidelity are deficient in this case.

While this has considerable entertainment value, its implications may apply to a number of combustion phenomena,

including, for example, the instability of chemical rocket engines.

Optical Activity in a Non-enantiomorphous Crystal Silver Gallium Sulphide

For the first time, optical activity¹⁻³ has been positively identified in a non-enantiomorphous crystal, that is, one which does not have left and right handed forms. observations are in agreement with the predictions of the theory of optical activity based on the gyration tensor.

The gyration tensor (an axial second rank tensor) is the lowest order tensor compatible with the observation that the sign of the optical rotatory power depends on the left or right handedness of the crystal axes but does not change when the direction of propagation is reversed. When the symmetry of this tensor is considered in relation to the point symmetry of the thirty-two crystal classes it is found that optical activity can only be present in fifteen of them $(1, 2, m, 222, mm2, 4, \overline{4}, 422, \overline{4}2m, 3, 32,$ 6, 622, 432 and 23). As far as can be ascertained optical activity has never been observed in the four non-enantiomorphous classes m, mm2, 4 and 42m. According to this theory the two bi-axial classes, m and mm2, would show rotation along the optic axes, provided that these are not in a plane of symmetry; unfortunately, no examples are known⁵. The two uniaxial classes, 4 and 42m, do not exhibit rotation along the optic axis because of the rotation-inversion symmetry. Optical activity should be present in other directions but it is masked by the much larger effects of birefringence. No evidence of optical activity has ever been reported in these two classes.

Silver gallium sulphide (AgGaS₂, class $\overline{42}$ m)⁵ is a yellow crystal with high refractive indices, transparent at wavelengths greater than 4800 Å. This crystal has been found to have the unusual property that the birefringence changes sign at about 4970 Å. At this wavelength the crystal is accidentally optically isotropic. This enables optical rotation to be measured with light of this wavelength in any direction. It can be shown from the form of the gyration tensor for class 42m that the optical rotatory power in a direction specified by direction cosines l_1 , l_2 , l_3 , with respect to the x, y and z axes, is

$$\rho = \pi g_{11}(l_1^2 - l_2^2)/\lambda_0 n$$

where g_{11} is an element of the gyration tensor, λ_0 is the free space wavelength and n is the refractive index. From this equation it can be seen that rotation along the x and y directions should be of equal magnitude and opposite sign. A direction lying in a symmetry plane should have no rotation.

These predictions have been verified. Plates of various thicknesses cut from a single crystal perpendicular to x or y directions show unambiguously a rotatory power of

522 degrees/mm at this wavelength, the signs of the rotation being opposite. No convention has yet been adopted to distinguish x and y and derive the absolute sign of g_{11} ; the magnitude of g_{11} is 3.88×10^{-3} . Plates cut perpendicular to the c axis show no rotation.

It is hoped that this observation will finally eradicate the notion that optical activity is exclusively related to

enantiomorphism.

I thank D. S. Robertson and H. A. Chedzey for growing the crystals and K. F. Hulme for helpful comments.

Composition of Velocities

In pre-relativity kinematics the directed quantity velocity is defined by v = dx/dt, a postulate which inherently specifies the law of composition as the vector, or parallelogram, law. In relativity kinematics the velocity of a point mobile P is still defined as the directed quantity the components of which are those of dx/dt, but it is no longer a vector obeying the parallelogram law of addition,

a point which will be stressed by writing \hat{v} .

In equations \hat{v} appears through the matrix $T(\hat{v})$, the pure Lorentz matrix describing the transformation between co-ordinate systems attached to P and to the observer, such that every point of the system attached to P is seen to be moving with velocity ϑ . In the P system a typical point, such as P itself, being stationary, will observe only passage of time, an observation denoted by $[\mathbf{0}, d\tau]$. The corresponding interval will be seen by the observer as $[\mathbf{dx}, \mathbf{d}t]$, where by the very definition of the motion $\theta = \mathbf{dx}/\mathbf{d}t$. The connexion between the observations is then

$$[d\mathbf{x},dt] = T(\hat{v})[\mathbf{o},d\tau]$$
 (1)

Special relativity, however, in addition to defining velocity through equation (1), also specifies its law of composition by extending equation (1) to read

$$[\mathbf{dx}, \mathbf{dt}] = T(\theta) [\mathbf{dy}, \mathbf{d\tau}] \tag{2}$$

a relation holding between space-time intervals as measured in the two systems for a point mobile moving with respect to both of them. The fact that equation (2) is usually deduced from the simpler postulate that the system of equations connecting such observations is linear does not alter the fact that it represents an additional postulate over and above equation (1).

Writing $\hat{w} = dx/dt$, $\hat{u} = dy/d\tau$, equation (2) can be shown to be equivalent to the matrix equation1

$$T(\hat{v})T(\hat{u}) = T(\hat{w})R(\Omega) \tag{3}$$

which demonstrates explicitly the relativity law of composition of velocity \hat{u} followed by velocity \hat{v} to give a resultant velocity \hat{w} . The matrix $R(\Omega)$, having the structure of a spatial rotation operator, is usually interpreted as demonstrating that successive pure Lorentz transformations induce a rotation of the spatial coordinate frame followed by a resultant pure Lorentz transformation. Equation (3) has the advantage over equation (2) of showing explicitly the appearance of this operator, necessitated by considerations of mathematical congruity.

Equation (3), as shown by its equivalent equation (2), is sufficient for equation (1), but not necessary. If the assumption of a linear system of equations existing between $[d\mathbf{x},dt]$ and $[d\mathbf{y},d\tau]$ is abandoned the way is clear for alternative hypotheses as to the composition of velocities. One in particular, which shows extraordinary promise, is to retain the matrix T(t) to represent a velocity t but to postulate the law of composition of velocities as

$$[T(\hat{v})]^{2}[T(\hat{u})]^{2} = [T(\hat{w})]^{2}[R(\Omega)]^{2}$$
 (4)

Structurally, equations (3) and (4) are similar and the solution of equation (4), that is, expression of \hat{w}, Ω , in terms of \hat{v}, \hat{u} can be obtained from the known solution of (3) by observing that

$$[T(\vartheta)]^2 = T \left[2\vartheta / \left(1 + \frac{|\vartheta|^2}{c^2} \right) \right] \tag{5}$$

a similar relation existing for $R(\Omega)$. Once again the factor $[R(\Omega)]^2$ is needed for mathematical congruity. \hat{w} has been defined as the resultant velocity but this time it is meaningless to explain away $R(\Omega)$ as representing a rotation of some spatial co-ordinate framework, but more logical to suppose Ω to characterize some as yet unidentified property of the mobile itself. Because $R(\Omega)$ has the structure of a rotation matrix, Ω itself is inherently an axial directed quantity, as opposed to the parameters $\hat{u}, \hat{v}, \hat{w}$, associated with T-matrices, which are inherently polar.

Thus the motion of a mobile is described by a polar parameter \hat{w} and an axial parameter Ω through the matrix $[T(\hat{w})]^2[R(\Omega)]^2$. If these parameters change, so that the descriptive matrix becomes $[T(\hat{w}+d\hat{w})]^2[R(\Omega+d\Omega)]^2$ then it is logical to connect the change with the externally applied force. If that force is purely polar, \hat{f} , the change matrix multiplier will be of type T and this condition lead to

$$\hat{f} = \frac{1 - \frac{|\hat{w}|^2}{c^2}}{1 + \frac{|\hat{w}|^2}{c^2}} \frac{d}{dt} \left\{ \frac{\hat{w}}{1 - \frac{|\hat{w}|^2}{c^2}} \right\}$$
(6)

This equation has been derived from purely kinematical considerations. As usual, equality of inertial and gravitational mass is assumed so that equation (6) is converted into the dynamical generalization of Newton's second law by multiplying each side by the mass of the mobile m_0 . The energy integral is then

$$m_0 \int \hat{f} \cdot d\mathbf{x} = m_0 c^2 \log \left(1 - \frac{|\dot{w}|^2}{c^2} \right)^{-\frac{1}{2}}$$

$$= \frac{1}{2} m_0 |\dot{w}|^2 + \frac{1}{2} m_0 \frac{|\dot{w}|^4}{c^2} + \dots$$
 (7)

Calculations based on equations (6) and (7) for \hat{f} obeying the inverse square law give the correct values for the advance of the perihelion and the bending of light.

Use of equation (4) in place of equation (3) originally arose in an as yet unpublished investigation of the possibility of representing an electrostatic field vector by a T-matrix and using equation (3) to depict its transformation by a velocity T-matrix into a field containing an electrokinetic T-matrix and a magnetic R-matrix.

Although the structural requirements of the physical problem were met, quantitative agreement was only secured when equation (3) was replaced by equation (4), or rather a slight variant of it, where if & characterizes the electric field

$$[T(\hat{v})]^2 [T(\hat{u})]^2 = R(\Omega) [T(\hat{g})]^2 R(\Omega)$$
 (8)

 $T(\hat{g})$ being the electrokinetic operator rather than $T(\hat{w})$.

Physical theory founded on equations (4) and (8) gives results very different to those of special relativity. In particular contraction in dimension is isotropic and charge decreases with motion by the contraction factor

$$\gamma = \left(1 - \frac{|\hat{w}|^2}{c^2}\right)^{-\frac{1}{2}}$$

Thus in applying equation (6) to the motion of a charged particle, rest charge q_0 , rest mass m_0 , in an electric field ℓ the force is $q_0 \gamma^{-1} \ell$ and the energy integral is now

$$q_0 \int \hat{e} \cdot d\mathbf{x} = m_0 c^2 (\gamma - 1) = \frac{1}{2} m_0 |\hat{w}|^2 + \frac{3}{8} m_0 \left| \frac{|\hat{w}|^4}{c^2} + \dots \right|$$
 (9)

which is just the result of special relativity!

A similar calculation for a transverse magnetic field once more yields the relativity formula, so that the new theory is entirely consistent with the formulae used in analysing particle accelerators.

It remains to investigate Ω in the kinematic case. Noting that the left hand sides of equations (4) and (8) are identical suggests that there might be a kinematic significance to equation (8) when θ and \hat{u} are both velocities. \hat{w} is then \hat{g} rotated as prescribed by $R(\Omega)$, the moduli, or speeds, being equal.

moduli, or speeds, being equal.

This suggests that the true motion \hat{w} of a particle of non-zero Ω might appear "aberrated" into an apparent velocity \hat{g} . If this be so, particles of the same \hat{w} but different Ω would present different \hat{g} . Thus for a given $|\Omega|$ but random direction for the axis of Ω , \hat{g} would lie within a cone of half-angle $|\Omega|$ centred on \hat{w} , or in other words its direction would be uncertain, although bounded.

Finally, two particles having the same apparent velocity θ cannot have different Ω because their trajectories would then diverge. This is an exclusion principle.

CHEMISTRY

Electrical Polarization and Microwave Absorption of Aluminium Acetylacetonate in Benzene Solution

STATIC dielectric constants and specific volumes have been measured for benzene solutions of aluminium acetylacetonate at 25°, 35°, 45° and 55° C. The dielectric constants and losses at frequencies of 9,133 and 24,560 Mc/s were also determined for benzene solutions of the aluminium chelate at 15°, 25° and 45° C. Total molar polarizations and dielectric relaxation times have been calculated from these data.

Aluminium acetylacetonate (J. T. Baker Chemical Co.) was repeatedly crystallized from benzene-petrolcum ether and then dried over phosphorus pentoxide under vacuum (melting point, 193.0°-193.5° C). The analysis

calculated for $Al(C_5H_7O_2)_3$ was carbon 55.55 per cent, hydrogen 6.52 per cent, and was found to be carbon 55.68 per cent and hydrogen 6.56 per cent by weight. Reagent grade benzene, free of thiophene (Fisher Scientific Co.), was fractionally distilled over lithium hydride and stored over 'Drierite' until immediately before measurement $(n_D^{200}, 1.50111).$

Static dielectric constants were measured with a heterodyne-beat apparatus (described in a report to be published) at 1 Mc/s. The dielectric constants and losses at the microwave frequencies were determined by using waveguide techniques described elsewhere1,2. The microwave results obtained from the solution studies were treated as described earlier3. The slopes of the straight lines thus obtained, a' corresponding to ϵ' and a''corresponding to ε", were plotted in Cole-Cole arcs to obtain the critical wavelengths, λ_m , the most probable relaxation times, τ_0 , the distribution parameters, α , and the arc intercepts at high frequency, a_{∞} . The values of these quantities are given in Tables 1 and 2. The concentration range in mole fraction of solute for the set of solutions examined is given in parentheses in Table 1. The total molar polarizations, $P_{2\infty}$, listed in Table 2, were calculated by the method of Halverstadt and Kumler⁵.

The absolute error in the $P_{2\infty}$ values of Table 2 was estimated to be ± 3 cc. An error analysis of these polarization values and the parameters from which they were deduced have not yet been published. The error in the to values of Table 2 was estimated to be ± 15 per cent.

Table 1. Slopes for the dependence of the diblectric constant and loss of aluminium acetylacetonate-benzene solutions (0-0-049) on mole fraction of solute

Frequency	1	5° C	28	5° C	45° C		
(Mc/s)	a'	a"	a'	a^*	a'	a"	
24,560	3.18	0.376	3.24	0.371	3.26	0.337	
9,133	3.52	0.329	3.48	0.260	3.41	0.174	
1	3.67		3.59		3.44		

Table 2. High frequency intercepts, critical wavelengths, relaxa -tion times, distribution parameters, and total moder polarizations of aluminium acetylacetonate in benzene solution

t (° C)	a_{∞}	λ_m (cm)	$\tau_0(\times 10^{-18}\mathrm{sec})$	α	$P_{z\infty}$ (cc)
15	2.87	1.56	8.3	0	
25	2.82	1.09	5.8	0.03	131.7
35					132.4
45	2.66	0.64	3-4	0	131.4
55					130.0

The static measurements confirm that aluminium acetylacetonate is non-polar. The change of polarization for a range of temperatures of 200° C is seen to be not more than 1 cc when these results are combined with the vapour phase total polarization value, 130.8 cc at about 240° C. The fact that aluminium acetylacetonate is nonpolar is significant because it has been found to exhibit considerable microwave loss in benzene solution (Table 1). For example, the losses observed at 9,133 and 24,560 Mc/s for a solution of about 0.05 mole fraction at 25° C were about ten times greater than those of the non-polar solvent, benzene. These losses are much too large to be accounted for by the presence of polar impurities in the starting materials or dissociation of the aluminium chelate in solution. Substantial dissociation in solution would have resulted in a measurable difference between the solution and vapour total polarization. Moreover, the infrared spectra of a number of metal acetylacetonates in solution show no evidence of absorption peaks resulting from dissociation products7. The observed dielectric losses therefore cannot be explained as the relaxation losses of rotating permanent dipoles. Any explanation of these losses must be in agreement with the decrease of loss with

increase of temperature, with the frequency dependence of the loss, and with the fact that the solution total polarization of the chelate does not differ significantly with the vapour phase value.

The molecular distortion mechanism suggested by Whiffen⁸ to account for the dielectric losses exhibited by benzene, carbon tetrachloride and other non-polar liquids cannot be invoked in the present case. This mechanism for the loss would lead to an appreciable difference between the solution total polarization and the vapour total polarization of aluminium acetylacetonate. contribution to the solution static polarization of about 11 cc is calculated from the extrapolated a_{∞} and the measured a_0 value (25° C). A solution total polarization 11 cc greater than that of the vapour would have been detected.

The thermal bending theory, considered as a possible explanation for the large differences between the total and electronic polarizations of a number of non-polar metal acetylacetonates, cannot explain these results. This theory postulates that the molecules bend considerably as a result of the energy imparted by thermal collisions and remain bent long enough to rotate like permanent dipoles in an applied static field, while still bent one way. The relaxation times found for the aluminium chelate in benzene solution (Table 2) are much too short to be consistent with such a picture.

The observed loss cannot be reconciled with the fact that it is the long wavelength tail of a vibrational, infrared absorption band which is being observed. If this were the case, an increase in the loss in the low frequency tail would be expected with increase in temperature because the line breadths of the infrared bands increase with tempera-

Recently, the structural details, as determined by X-ray crystallography, of thirteen acetylacetone chelates have been summarized10. In all cases, the acetylacetone portion of the chelate ring is planar within the experimental error of the data. The metal atom may, however, deviate from the plane of the chelate ring by as much as 0·1-0·5 Å, giving the chelate considerable flexibility at the metal. This fact suggests that a relatively low frequency vibration of the rings about the aluminium atom as a centre may be an important motion to consider in arriving at a plausible explanation of the observed loss of aluminium acetylacetonate in solution and its frequency dependence. At present, microwave absorption measurements are being made on solutions of other non-polar co-ordination compounds (for example, beryllium-, iron (III)-, and thorium (IV) acetylacetonate, and a number of transplanar complexes of copper and nickel). The tetrahedral, octahedral, cubic and planar complexes are being studied in the hope of throwing additional light on the problem.

Catalytic Carbon-Carbon Bond Formation from Methylene Chloride over Evaporated Titanium Films

During a study of the reactions of alkyl chlorides at the surfaces of evaporated metal films we observed that a gas phase mixture of methylene chloride and hydrogen reacted in the temperature range 200°–300° C at the surface of evaporated titanium to yield a variety of hydrocarbon products from C_1 to a waxy polymer. Out of every hundred carbon atoms entering the reaction, not less than eighty entered products of C_2 or higher. We wish to direct attention to this reaction because a polymerization starting from a C_1 parent is unusual.

The reactions were carried out in a static system with initial methylene chloride and hydrogen pressures (measured at 0° C) of 6·0 and 60 torr, respectively. The apparatus and technique used were similar to those previously used for reactions over metal films (ref. 1 and unpublished results). Gas phase analysis was by means of mass spectrometry and vapour phase chromatography. Titanium films were in the range 5–10 mg, and the effective surface area under reaction conditions was estimated by the Brunauer–Emmett–Teller method to be about 500 cm². The reaction volume was 180 ml., and a standard reaction mixture contained $3\cdot84\times10^{19}$ molecules of methylene chloride.

The composition of the products in typical reaction conditions is given in Table 1. Usually, the reaction products fell into two categories: first, gas phase hydrocarbon products in the range C1-C5 were observed by analysis of the gase phase; and second, a colourless filmlike material which was presumably highly polymeric was recovered from the surface of the titanium after the reaction by treatment of the metal with dilute hydrofluoric acid. The material recovered in this way was found to be amorphous when examined with transmission electron diffraction in an electron microscope. nature of the experiment did not allow sufficient material to be produced for more detailed study. Examination of the titanium itself after the reaction by transmission electron diffraction gave a pattern that indexed as TiH1.0, using evaporated gold as a calibrating standard. Table 1 shows that the total number of carbon atoms which enter the polymer is in approximate agreement with the estimated weight of polymer. For example, if the polymer is assumed to be free of chlorine and of approximate composition $(CH_2)_n$, 330×10^{-7} moles of incorporated carbon corresponds to a polymer weight of about 0.5 mg. Not all the polymer could be recovered, but the total amount was estimated to be of the order of 1 mg.

The extensive range of products suggests that the mechanism of this reaction may well be a complex one. A detailed account will be published of the results of an investigation into the reaction mechanism. present purpose, however, we may summarize the following relevant observations. (a) Ethylene and propylene were formed with about the same activation energy (~6 kcal mole-1), and methane and the small amounts of ethane and propane were also all formed with about the same activation energy (~ 11 kcal mole⁻¹). (b) In a similar reaction with deuterium in the place of hydrogen, most of the ethylene was produced as C₂H₄. (c) Reactions at very low gas pressures (in the mtorr region) showed that surface hydrogen was not required for the process of hydrocarbon desorption, and the surface stoichiometry suggested that CH2 residues together with some more extensively dehydrogenated species were present on the surface. From these observations we tentatively suggest that the chief reaction path can be described by the following types of reactions. The notation is used where $(CH_2)_8$ means a methylene group chemisorbed at the titanium surface.

$$CH_2Cl_2 \rightarrow (CH_2)_s + 2(Cl)_s$$
 (1)

$$(\mathrm{CH_2})_s + \mathrm{CH_2Cl_2} \rightarrow \begin{bmatrix} \mathrm{CH_2}. \\ | & + & \mathrm{CH_2Cl_2} \\ \mathrm{surface}. \end{bmatrix} \rightarrow \\ (\mathrm{CH_3CH})_s + 2(\mathrm{Cl})_s \quad (2)$$

$$(CH_3CH)_{\delta} \rightarrow C_2H_4$$
 (3)

$$(Cl)_s \xrightarrow{H_s} HCl$$
 (4)

The residue $(CH_3CH)_8$ may react further with CH_2Cl_2 to give a C_3 residue. On this basis, the general propagation step is

$$(CH_3(CH_2)_nCH)_s + CH_2Cl_2 \rightarrow (CH_3(CH_2)_{n+1}CH)_s + 2(Cl)_s$$

The entities written within square brackets in reaction (2) are meant to indicate that a quasi free radical may be involved in the addition step, although this may only occur as the transition state is approached. We suggest that the saturates are formed by inter-residue hydrogen transfer reactions.

Binuclear Carbonato-complex of Chromium (II)

With few exceptions, chromium (II) complexes can be simply classified according to their colours and magnetic moments. Most are blue or purple with magnetic moments which correspond to four unpaired electrons for each metal ion, but some salts of carboxylic acids are red or brown in colour and diamagnetic. Chromous acetate has been shown to possess a dinuclear structure with a short metalmetal bond. One species which seems to fall outside this classification is the product of the interaction of chromium (II) and carbonate ion. The simple colourless carbonate is soluble in excess aqueous carbonate media to give yellow solutions, from which yellow-brown complexes can be crystallized, such as Na₂Cr(CO₃)₂.10H₂O, Na₂Cr(CO₃)₂.H₂O, K₂Cr(CO₃)₂.3H₂O, (NH₄)₂Cr(CO₃)₂.H₂O (ref. 2). We have examined the yellow complex in aqueous solution by a spectrophotometric method and have shown that it contains two atoms of chromium per complex ion.

The visible spectra of chromous acetate and of the carbonate complex are shown in Fig. 1. By choosing the correct ratio of concentrations of acetate to bicarbonate, it is possible to prepare solutions with intermediate

Table 1. Typical distribution of products from the reaction of methylene chloride on evaporated titanium at 275° c

Product	CH4	CH ₂ Cl	Total C ₁	C_2H_4	C_2H_4	Total C ₁	C_3H_5	C_2H_8	Total C ₃	Total C ₄ -C ₅	Polymer (by) mass balance
Carbon appearing in indicated product (mole × 107)	60	11	71	55	19	74	22	8	30	Approx. 10	Approx. 330
Total CH _* Cl _* reacted = 51	6 × 10-7	mole.						•			

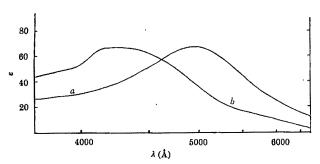

Fig. 1. Absorption spectra of chromium (II), (a) in acetate buffer medium, NaOAc 1.0 molar, HOAo 1.0 molar, chromium (II) 4×10^{-3} molar; (b) in bicarbonate medium, pH 7.2, potassium bicarbonate 1.0 molar, ammonium chloride 1.0 molar, chromium (II) 4×10^{-3} molar.

spectra, which must contain mixed acetato-carbonato complexes. (There is no isosbestic point.) At the wavelength 4340 A, the extinction coefficient of the pure carbonato complex exceeds that of the acetate, while at 5100 Å the reverse is true. If in a mixture of complexes the total chromium concentration is varied, the ratio of absorbances at these two wavelengths remains constant; therefore the relative proportions of complexes are constant, and the number of chromium atoms in each must be the same. Otherwise, with increasing total chromium, equilibria of the type in equation (1) would be displaced to the right or left, according to whether n is greater or less than two

$$n \operatorname{Cr}_{2}(\operatorname{OAc})_{x}^{(4-x)+} + 2y\operatorname{CO}_{3}^{=} \rightleftharpoons \\ 2\operatorname{Cr}_{n}(\operatorname{CO}_{3})_{y}^{2(n-y)+} + nx\operatorname{OAc}^{-}$$
 (1)

The number of carbonate ions in the yellow complex has not been determined, but it has been observed that, in mixtures of complexes with a constant ratio of free acetate and bicarbonate ions, the ratio of absorbancies at 4340 and 5100 Å is independent of the total concentration of these ions, for example, $[OAc^-] = 10 [HCO_3^-] = 0.2$ -1.4 molar. This suggests that replacement is a one-for-one process, the total number of ligand ions being the same in each dinuclear complex species.

Further speculation on the nature of the carbonatocomplex would be premature, but it may be pointed out that the spectrum is similar to that of chromous acetate although it is shifted to shorter wavelengths. Both spectra seem to consist chiefly of two broad bands (see Dubicki and Martin³ for an analysis of the acetate spectrum), giving a pronounced "tail" on the low wavelength side. It is also interesting to note that the carbonato complex is comparatively resistant to oxidation, even more so than the acetate. A dilute solution exposed to air takes several minutes to assume the green colour of aqueous chromium (III).

The stability of the complex with respect to dissociation can be judged from its reactions with different ligands. At pH 7.72 it is completely decomposed into monomeric chromium(II) by EDTA and 2,2'-dipyridyl in stoichiometric amounts. On the other hand, glycollic, tartaric, citric and iminodiacetic acids have no effect in concentrations up to 0.1 molar. Pyridine has no effect on the visible spectrum in concentrations even up to 1 molar.

Nitrilotriacetic acid (H₃L) produces partial dissociation into monomer, and further spectrophotometric measurements indicate the following equilibrium

$$\operatorname{Cr}_2(\operatorname{CO}_3)_y(4-2y) + 2\operatorname{L}^{3-} \rightleftharpoons 2\operatorname{CrL}^{-} + y \operatorname{CO}_3^{=}$$

with $K = [CrL^-]^2/[Cr_2(CO_3)_y(4-2y)+][HL^-]^2 = 0.6 \pm 0.2$ l./mole at pH 7.72 and 25° C in I molar potassium bicarbonate, 1 molar ammonium chloride.

It was further observed that K varies as the inverse square of bicarbonate concentration

$$\dot{K}[\text{HCO}_3^-]^2 = 0.45 \pm 0.2 \text{ molar}$$

At first sight this seems to imply that two carbonate or bicarbonate ions separate from every molecule of the dinuclear complex, that is y=2. This conclusion is not certain, however, because at the high bicarbonate concentrations used, there is the possibility of association between the mononuclear CrL- and bicarbonate ion. This is suggested by the fact that a number of nitrilotriacetato complexes ML- have been shown to give hydroxo derivatives with formation constants $\beta_{\text{MLOH}} = [\text{MLOH}^{=}]/[\text{ML}^{-}][\text{OH}^{-}]$ as high as 100 l./mole.

Further work on the acetate-carbonate system is in progress.

Observations on the Dissolution Potential of Oxalic Acid

RECENTLY, Rastogi, Batra and Dass¹ have reported that potential differences are produced when crystals of an electrolyte just appear or when they are allowed to dis-The former has been called the precipitation potential and the latter the dissolution potential. One of the important conclusions of this study is that the dissolution potential of an electrolyte, in an aqueous solution of the same, is a function of the concentration and that its value increases as the dilution is increased. The dissolution potential was also seen to increase systematically in most cases as the temperature of the water is increased. This seems logical, for the dissolution potential must be related in some manner to the solubility of the electrolyte as the term implies.

Because this is a new effect, we wished to see whether there is any quantitative relationship between the solubility of an electrolyte and its measured dissolution potential. For this purpose measurements of dissolution potential were made for oxalic acid. Our method was essentially the same as described by Rastogi et al.1. A vacuum tube voltmeter (Philips model GM6000/90) with a least count of ± 10 mV was used. Experiments were conducted at four temperatures, and at five concentrations of oxalic acid with the temperature constant at 40° C. The experiments were repeated several times to check the reproducibility of the results. The data are summarized in Table 1.

Table 1. DISSOLUTION POTENTIAL OF OXALIC ACID AS INFLUENCED BY TEMPERATURE AND CONCENTRATION

Temperature of water (°C)	Dissolution potential (mV)	Concentration of oxalic acid	Dissolution potential (mV)*
31	210	0·1 normal	. 70
40	200	0.01 normal	110
50	200	0.001 normal :	160
60 .	220	0.0001 normal	190
		0.00001 normal	200

* Temperature kept constant at 40° C.

Table I shows that although there is a progressive increase in the value of dissolution potential with the decrease in concentration of the solute, there is practically no variation of dissolution potential with increasing temperature. If the dissolution potential is a function of the solubility it is imperative that the dissolution potential must also increase with increase in temperature because there is a nearly four-fold increase in the solubility2 of oxalic acid as the temperature is raised from 31° to 60° C. To us therefore the relationship between dissolution potential and solubility is not obvious.

Rates of Adsorption of Wetting Agents and Detergents at 'Graphon' Solution Interface

THE sodium salts of α-sulpho fatty esters (R CH(SO₃Na)-COOR') behave as either wetting agents or as detergents depending on the length of the acid and alcohol chains (R and R'). In practice, if either R or R' is long and the other chain short, then the surfactant behaves as a detergent; if both R and R' are of the same medium chain length, then the surfactant functions as a wetting agent. The ability of a compound to act as a detergent was rated on the basis of 'Terg-O-Tometer' tests and wetting ability was assessed using the Draves test^{1,2}.

A physical chemical approach was sought to uncover the differences between wetting agents and detergents. Thermodynamic factors, such as co-areas at the air/water and oil/water interfaces and heats of adsorption at the solid/liquid interface (refs. 3 and 4 and unpublished work by A. C. Zettlemoyer), did not differ significantly. was recognized that a kinetic factor might distinguish between the two varieties of surfactants. measurement to make was the rate of adsorption to the 'Graphon' (a graphitized carbon black with B.E.T. nitrogen surface area 104 m²/g) surface by following the conductivity decrease with time after the graphitic powder was dispersed into the surfactant solutions (above their critical micelle concentrations, CMCs).

The α -sulpho fatty esters studied were prepared by

Stirton, Weil and their co-workers (refs. 3 and 4) and were purified; they are listed in Table 1.

Table 1. THE a-SULPHO ESTER SURFACTANTS STUDIED

Compound	\boldsymbol{R}	R'	0.01 carbon atoms $R+R'+2$
Wetting agents		_	
(1) Sodium hexyl a-sulphopelargonate (Na Hex aS Pelar)	7	6	15
(2) Sodium heptyl a-sulphopelargonate (Na Hep as Pelar)	7	7	16
(3) Sodium octyl a-sulphopelargonate (Na Oct as Pelar)	7	8	17
Detergents			
(4) Sodium methyl a-sulphomyristate (Na Me aS M)	12	1	15
(5) Sodium methyl a-sulphopalmitate (Na Me aS Palm)	14	1	17
(6) Sodium ethyl a-sulphopalmitate (Na Et as Palm)	14	2	18

Thus compounds 1,4 and 3,5 form exact pairs as far as the number of carbon atoms are concerned. Solutions of 5.8×10^{-3} moles (about 0.2 per cent) (well above their CMCs) were prepared with triply distilled water and bulbs containing 1 g of activated 'Graphon' (evacuated at 105° C in 10-5 torr vacuum for 4 h and then sealed off) were broken in 150 cc of the surfactant solutions, with a plastic enclosed magnetic stirrer in operation. All the experiments were done at a temperature of $25^{\circ} \pm 0.1^{\circ}$ C. All the The reduced conductances—that is, the ratio of measured (Ω) to initial conductance $(\Omega_0)-$ are plotted against time in Fig. 1. The plots indicate a clear difference between the two varieties of surfactants. The wetting agent

solutions reached a minimum conductance in about 3-7 min while the detergent solutions required about 20-25 min.

It is doubted that demicellization is the slow process in the case of detergents because demicellization rates of surfactants are reported to be almost instantaneous⁵. A more probable reason for this interesting observation is that the rates of diffusion of the detergent type species to the surface are slower than for the wetting type. For the detergent solutions, a slow ageing and thus a slow decrease in surface tension with time was also noted at the air/water interface (ref. 3 and unpublished work); no such ageing effect was noted for the wetting agent type.

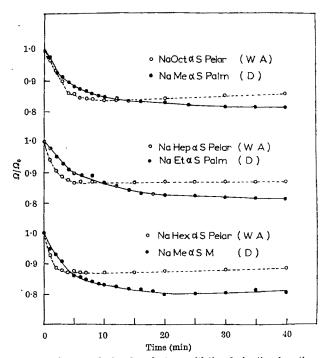

Fig. 1. Changes of reduced conductance with time during the adsorption of wetting agents and detergents at 'Graphon'/solution interface. O. Wetting agents (WA); •, detergents (D).

It is known that the adsorption of surfactant anions takes place with the hydrocarbon portion of the anion oriented toward the hydrophobic surface of 'Graphon' and the polar group projected into the bulk liquid phase. Another possible reason for the slow rates of adsorption of the detergent type species is because the chains R and R' are of different length; re-arrangement of the ions for the proper orientation at the interface may be delayed. In other words, the sticking coefficient of the detergent type species could be lower than those of the wetting agent type.

Diffusion measurements with radioactively labelled species would allow these two factors, diffusion rates and the sticking factor to be separated.

This work was done under contract with the US Department of Agriculture.

BIOLOGY

Haemoglobin Variation in Anadara trapezia

THE most common respiratory pigment among the molluses is haemocyanin, which is widely distributed among the gastropods, cephalopods and amphineurans. Most bivalves lack a respiratory pigment, but, if present, the pigment is haemoglobin, which can be found in muscle tissue, in haemocoelic crythrocytes or dissolved in the haemolymph¹. In Anadara trapezia (Deshayes) (Mollusca, Bivalvia), an arcid clam, haemoglobin is present in haemocoelic crythrocytes.

Haemoglobin from some arcid clams has been shown to be heterogeneous. Yagi et al.² showed, by moving boundary electrophoresis (Tiselius apparatus), that the haemoglobin of Anadara inflata contained at least three components. Using starch gel electrophoresis, Manwell¹ showed that the haemoglobin from two arcid clams, Noetia ponderosa and Anadara transversa, was heterogeneous with two principal components present in approximately equal proportions. This communication reports what are probably genetically controlled variations in the haemoglobins of a population of A. trapezia from Sydney. A study of variations between geographically separated populations is in progress.

Specimens of A. trapezia were collected from Gunnamatta Bay in Port Hacking (about 20 miles south of Sydney) and kept in aerated aquaria until they could be bled. Haemolymph was withdrawn from the pallial sinuses of each animal with a hypodermic syringe and each sample was centrifuged at 3,000 r.p.m. for 10 min. The supernatant was discarded. The cells were washed three times with 3 per cent sodium chloride solution and were lysed by alternate freezing and thawing. After centrifugation the cell debris was discarded and the supernatant haemoglobin solution was retained for electrophoresis.

The haemoglobin solutions were immediately subjected to electrophoresis on 'Cellogel' strips (Chemetron, Milan) in a Kohn electrophoresis apparatus operating at 400 V. Satisfactory resolution of the chief haemoglobin fractions was obtained with three buffer systems: (a) the tris (hydroxymethyl) aminomethane (tris)-ethylenediaminetetraacetic acid (EDTA)-boric acid buffer (pH 9.5) of Gelman³; (b) the tris-EDTA-boric acid buffer (pH 9.2) of Aronsson and Grönwall4; and (c) the tris-hydrochloric acid buffer (pH 8.2) of Bates and Bower⁵. separation of the haemoglobin fractions was obtained in 1-1.5 h using the Gelman buffer, whereas 4 h were necessary for separation using the buffers of Aronsson and Grönwall and of Bates and Bower. Although the haemoglobin fractions were immediately detectable on the strips, they were permanently stained with a saturated solution of 'Amidoschwarz 10B' (Merck). The strips were then sealed, together with a little 50 per cent methanol, in polyethylene.

The haemoglobin samples showed either two or three principal bands, which were examined in detail, and up to three "trace" bands, which were omitted from this study. The principal bands, labelled Hb1, Hb2a and Hb2b, occurred in three patterns (as shown in Fig. 1, patterns 1, 2 and 3). All three patterns contained band Hb1. Pattern 1 contained band Hb2a, pattern 2 contained band Hb2b and pattern 3 contained both bands Hb2a and Hb2b.

The frequency distribution of the band patterns in the population of 188 A. trapezia suggests that the bands Hb2a and Hb2b are genetically determined by one pair

Table 1. Observed and expected frequency distribution (hardyweinberg) of haemoglobin electrophoretic patterns in a population of $A.\ trapezia$

	Pattern 1	Pattern 2	Pattern 3
Observed	8	114	66
Expected	8·93	114·96	64-11

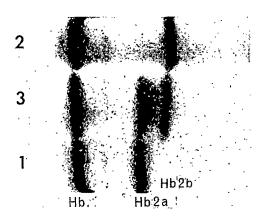

Fig. 1. Electrophoretic patterns (1, 2 and 3) of haemoglobins (Hb1, Hb2a, and Hb2b) from A. trapezia (tris-EDTA-boric acid buffer, pH 9.5).

of alleles. For, if pattern 1 is that of the homozygote Hb2a, Hb2a, pattern 2 is that of the homozygote Hb2b, Hb2b, and pattern 3 is that of the heterozygote Hb2a, Hb2b, the population should closely approximate the corresponding Hardy-Weinberg frequency distribution. It can be seen in Table 1 that this is the case, for the χ^2 value is 0·16 (P=0.7). Thus it seems that these band patterns are genetically determined by one pair of alleles.

Blood Group Studies of the "Gene Bank" Sheep at Whipsnade Park

ROWLANDS¹ reported that the Zoological Society of London was establishing a "Gene Bank" composed of some rare breeds of domesticated animals which were in danger of becoming extinct. We therefore took the opportunity of investigating the blood groups of some of the sheep which were to form the nucleus of the "Gene Bank" sheep flocks.

Blood samples were collected with and without anti-coagulant. Using a haemolytic test^{2,3}, the red cells were tested for the presence of R and O blood group substances and the sera were tested for the presence of anti-R anti-body. Red cell potassium types^{4,5} were determined using a flame photometer, and the serum transferrin^{6,7} and red cell haemoglobin^{5,8} types were determined by starch gel electrophoresis. The sera and lysates made from washed red cells were stored at -20° C for about a year; they were then tested for electrophoretic variation in the recently discovered serum albumin⁹ and A esterase¹⁰ systems and also in the red cell carbonic anhydrase and "X" protein systems¹⁰.

Table 1 summarizes the results obtained. All the Cotswold sheep were of blood group R. In the other breeds, however, both R and O individuals were found, and in the Portland breed there was also one group i individual. All the group O sheep had anti-R present in their sera. The fast haemoglobin variant A was only found in four of the Woodlands Whiteface sheep; all other sheep were

The numbers listed under each phenotype indicate the number of sheep in the breed which were of that particular type.

of type B. The red cells of all the Norfolk Horned sheep were of high potassium type (HK), while those of all the Cotswolds were low potassium type (LK); individuals of both potassium types were found in the other breeds. A red cell carbonic anhydrase variant (CA-F) of faster electrophoretic mobility than the commonly occurring one was found in Merino, Columbia and Targhee sheep breeds in the USA (ref. 10), but it was not present in any of the Whipsnade sheep, which were all of the slow CA-S type. In fact, the CA^F allele has not yet been found in any of the breeds tested in Great Britain (Clun Forest, Welsh Mountain, Dorset Horn, Soay, Finnish Landrace, my unpublished results). The non-haemoglobin red cell protein, provisionally called "X", was found in one or more sheep in each of the breeds except the Cotswold. No unusual serum transferrin types were found, but four (TfA, B, C and D) of the commonly described six transferrin alleles were detected. A esterase activity (EsA+) was found in the serum of 50 per cent of the Lincoln Longwool sheep and in one Portland sheep; all other sheep were negative for this enzyme (EsA-). All the sheep were of the same albumin phenotype, presumably the S type described by Efremov and Braend's.

It is not possible in this article to do more than simply report the occurrence of these factors in the various breeds and to note that no unusual factors were detected. No conclusions as to breed origins or relationships can be drawn from such limited material. It should also be understood that the blood groups of these few individuals may not necessarily be truly representative of the breeds studied. The absence of any particular factor does not mean that it might not have been found had larger numbers of each breed of sheep been tested. I felt, however, that it might be of some interest to place on record those factors which were present in these breeds at the outset of the society's breeding scheme.

I thank Dr I. W. Rowlands and Mr E. H. Tong for allowing me access to the sheep, and Mrs V. A. Herbert and Mr L. Kilgour for technical assistance. I also thank Dr J. G. Hall for providing the transferrin reference samples and for checking my transferrin results.

Modified Carbohydrate Metabolism in the Tropical Swamp Worm Alma emini

A TROPICAL papyrus swamp is a difficult environment for animal life, the mud in which the swamp worms (Oligochaeta, Glossoscolecidae) live is both anaerobic and In order to obtain atmospheric strongly reducing1. oxygen in these conditions, the dorsal surface of the hind end of Alma is specially modified as a respiratory organ which is exposed above the surface of the mud1. It is quite likely that Alma is biochemically adapted to life in the swamp environment.

Worms were collected from a swamp near Kampala and kept in macerated blotting paper soaked in tap water. Into this they discharged their gut contents. Alma were kept in very fine sand (decarbonized and sieved swamp mud) with access to air they survived for at least a month without food. During this time part of the body glycogen was broken down, but there were no significant changes in body fat. In anaerobic water, however, worms survived for only 3 days, but in swamp mud below an atmosphere of nitrogen they survived somewhat longer. The swamp worm is therefore primarily an aerobe.

Ethanol extracts of Alma kept in macerated paper with access to air were purified on resin and separated by paper and silicic acid column chromatography. Large amounts of succinic and malic acids were present (3.3 and 2.4 µmoles/g fresh weight) and some fumaric acid. Similar amounts were present in worms kept in swamp mud below air. In anaerobic water the malic acid almost disappeared within 12 h but the amount of succinic acid increased slightly. Malic acid probably acts as a hydrogen acceptor in anaerobic conditions while succinic acid may be a central molecule in anaerobic metabolism. Pyruvic and α-ketoglutaric acids were present in aerobic conditions and both decreased in anaerobic conditions.

Addition of isocitric, a-ketoglutaric, succinic and malic acids (in the presence of antibiotics) stimulated oxygen consumption in chopped Alma, in vitro, and fluoroacetic acid partially inhibited it. This suggests that the citric acid cycle is functioning. Citric, fumaric and oxaloacetic acids were without effect on in vitro respiration. But the respiratory quotient of whole worms measured in Warburg manometers was about 0.5, which is lower than that usually associated with utilization of fats. Analysis of the medium in which worms had been kept in aerobic conditions failed to show organic products. The large numbers of bacteria present probably destroyed any organic molecules formed by the worms: in the presence of 1 g/l. of penicillin and 0.5 g/l. of streptomycin, volatile fatty acids were found in the water. Gas chromatography of the free fatty acids on 5 per cent FFAP on 'Aeropack 30', 100/120 mesh (Varian aerograph) showed acetic, propionic and a small quantity of a branched C₅ fatty acid (either 2-methyl or 3-methyl butyric acid, but these acids could not be resolved with the available equipment). The results imply that in aerobic conditions there is a partial aerobic fermentation. It was not, however, possible to sterilize worms in order to repeat this observation in the absence of antibiotics.

In anaerobic conditions, acetic, propionic and the C_5 fatty acid were formed (ratio 1:10:0.8) together with traces of butyric acid and branched C6 fatty acid, both in the presence and absence of antibiotics. acids accounted for almost 100 per cent of the glycogen broken down in anaerobic conditions. Traces of acetoin were present, but other chemical tests for possible end products, including lactic acid, were negative. Succinic acid was only found in the medium if the worms had begun to disintegrate.

The swamp worm thus has a type of metabolism that resembles most closely the metabolism of certain parasitic worms, for example Ascaris lumbricoides. This resemblance may represent a convergent biochemical evolution in animals that have become adapted to low oxygen levels or quite anaerobic conditions. Certain aquatic pulmonate snails produce acetic and propionic acids in anaerobic conditions² and it seems highly likely that other interesting metabolic pathways exist in free-living invertebrate animals that have become adapted to a scarcity, or complete absence, of oxygen.

Displacement and De-arousal

A RECENT communication by Delius¹ calls for some comment. Delius regards displacement behaviour as essentially made up of actions which are related to going to sleep. He therefore interprets displacement behaviour as a homeostatic mechanism in which "de-arousal" actions are called into play to counteract the excessive arousal occasioned by the conflict or thwarting situation to which the animal is exposed.

If this interpretation is correct, then clearly it must be applicable to displacement behaviour in general, and not only to a small number of selected cases. Displacement grooming in rats and cats are two of the cases cited by Delius in support of his views. Bolles² has shown that while rats may groom at almost any time, they are particularly prone to do so before going to rest and, to this rather limited extent, displacement grooming in Rattus norvegicus accords with Delius's views. I know of no study in eats comparable with that of Bolles, and while it is perfectly true that a cat does frequently groom before sleeping, grooming is also a normal accompaniment of waking up. In the absence of quantitative data, there is no justification for regarding grooming in cats as a de-arousal rather than an arousal action. In Cricetomys gambianus, however, grooming is an activity characteristic of arousal from the day's rest in preparation for the night's activity. It is therefore definitely not a de-arousal action and yet, in this species also, it is the predominant displacement activity³. In rats, cats and *Cricetomys* the factor which determines that grooming should be the chief displacement activity must therefore be sought elsewhere than in its relations to arousal or de-arousal. A comparison with two species in which grooming is not a very frequent activity is of some relevance. Xerus erythropus and

Suricata suricatta are both burrowing animals with rather coarse fur which is groomed much less extensively than in any of the three species previously considered. Both, however, are enthusiastic excavators. In Xerus, digging is predominantly an activity connected with burrowing, but in Suricata its predominant function is in food finding. In both species digging is the commonest displacement activity and I have not seen displacement grooming in These facts all suggest that the factor which decides what action shall be performed in a displacement context relates to its importance in the life of the animal and the frequency with which it is performed in its normal context, rather than its relation to going to sleep. If Delius's interpretation were correct, one would expect turning round in a circle to be the common canine displacement behaviour, for this action so commonly precedes settling to rest. I cannot, however, recollect ever having seen displacement circling in a dog.

Tinbergen4 long ago suggested that displacement behaviour has some therapeutic function, which serves to protect the central nervous system from over-activity and provides what in ourselves would be described as "relief of tension". Delius's view is, in a sense, an extension of this idea and an attempt to make it more precise. The attempt is laudable but I believe the interpretation put forward is mistaken. If we accept the disinhibition theory^{5,6} as providing at least a partial explanation of displacement behaviour, then it is easy to see why the actions performed should so often be those which are of very frequent cocurrence in the normal behavioural repertoire. The high frequency patterns are the ones which the animal is almost always ready to perform provided they are not inhibited by the activation of some other pattern with a higher urgency. They are therefore the ones most likely to appear if the currently activated patterns are suddenly switched off, with consequent cancellation of inhibitory effect on the high frequency pattern. Moreover, there is no need to invoke a necessary relation to de-arousal to account for the postulated tranquillizing effect of displacement behaviour. Once the latter is switched on, it is to be expected that it will, in its turn, inhibit the frustrated action and so bring about the required reduction in excitatory level. How beneficial this may be to the animal will, of course, depend on how extensive and how lasting is the effect produced. If it were very transitory, the status quo would merely be restored, but in a dynamic context even a fairly brief pause may permit changes in the external situation to occur and would at least allow the animal's central nervous system to re-assess the total situation from an altered "viewpoint"—that is, with a different excitatory/inhibitory balance in the relevant areas.

Clearly if the tranquillizing effect is indeed a reality and if a species is likely to show either of two displacement actions, one of which is a more effective tranquillizer than the other, then there will be selection in favour of the latter. If linkage with de-arousal were the basis for the greater tranquillization, then the situation postulated by Delius would result. The data available do not, of course, prove that this has never happened: the cases cited here, however, suggest that linkage with de-arousal has not been a factor of great importance in the evolutionary history of displacement behaviour.

Effect of Colchicine on Meiosis of Hexaploid Wheat

HEXAPLOID wheat, *Triticum aestivum*, behaves cytologically as a diploid organism in that only bivalents are formed at meiosis. This diploid behaviour is principally the result of the activity of a gene or genes in the long arm of chromosome 5B (refs. 1-4). In the absence of this gene or genes multivalents are formed involving homoeologous chromosomes⁵.

Feldman⁶ has demonstrated that an increased dosage of this gene or genes results in asynapsis, interlocking of bivalents and some multivalent formation. The hypothesis put forward to account for these various behaviours was that in the absence of 5B both homologues and homoeologues are associated premeiotically; with the normal two doses of 5B, however, this association is restricted to homologues; with six doses of the long arm of 5B, or four doses at extreme temperatures, there is no premeiotic association, all chromosomes being randomly arranged before meiosis.

The phenomena of asynapsis and interlocking of bivalents were also observed by Barber' in Fritillaria meleagris treated with colchicine before meiosis. Because of the similarities observed in these dissimilar experiments colchicine was applied to hexaploid wheat shortly before the onset of meiosis. Plants of the variety 'Chinese Spring' grown in a glasshouse at approximately 20° C were used. A single application of approximately 0.25 ml. of either a 1 per cent or a 2.5 per cent solution of colchicine was injected into tillers above the tip of the immature spike by means of a hypodermic syringe.

Spikes were subsequently collected for meiotic study some days later, fixed in Carnoy's 6:3:1 and anthers were stained in acetocarmine.

From a spike fixed 7 days after treatment with colchicine anthers containing pollen mother cells (PMCs) with twice the normal number of chromosomes at metaphase I were obtained from three different florets. These dodecaploid cells apparently arose by means of C mitosis as described by Levan⁸. Thus the last premeiotic mitosis apparently took place about 7 days before metaphase I of meiosis in these cases. The uniformity of PMCs with eighty-four chromosomes in this material indicates that the last premeiotic mitosis is fairly well synchronized in all cells of the same anther.

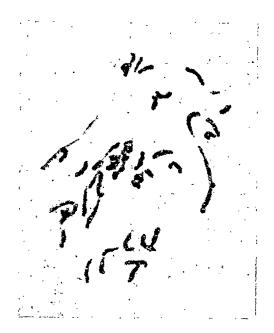

Fig. 1. Metaphase. of meiosis of a $6\times$ cell after treatment with colchicine, showing marked asynapsis and one trivalent.

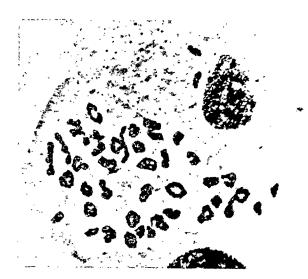

Fig. 2. Metaphase I of meiosis of a $12\times$ cell after treatment with colchicine, showing thirty-eight bivalents and eight univalents. Six of the univalents are obviously in three groups of two morphologically similar chromosomes.

In eight different spikes fixed 3-6 days after colchicino treatment anthers possessing PMCs with the normal forty-two chromosomes at metaphase I were observed. Thus in these cases colchicine had been applied after completion of the last premeiotic mitosis. In these cells, asynapsis and multivalent formation were observed. Multivalent formation was quite infrequent, only an occasional trivalent or quadrivalent being observed (Fig. 1). The mean pairing observed in these cells, as shown in Table 1, is slightly lower than that observed by Feldman's in plants with six doses of the gene or genes in the long arm of chromosome 5B.

Table 1. Mean and range of chromosomal pairing at metaphase I of meiosis in plants treated with colchicine

Type of cell	No. of cells	Univalents	Bivalents	Trivalents	Quadri- valents
6×	50	21·28 (12-36)	10·32 (3-15)		0·02 (0-1)
12×	50	8·32 (2-26)	37·38 (29–40)	0·04 (0-1)	0.20 (0-2)

From these observations it can be concluded that colchicine applied before meiosis inhibits premeiotic association of homologues.

The dodecaploid cells chiefly possessed bivalents (Fig. 2), with only an occasional multivalent as shown in Table 1. Multivalents find a ready explanation in these cells, for homologues are present in four doses. The scarcity of multivalents may be explained by the presence of colchicine. It is known that colchicine persisted in this material, for double dodecaploid cells undergoing C mitosis have also been observed in these anthers. Colchicine presumably suppresses quadrivalent formation by preventing the homologues associating into fours. Thus multivalent formation is limited to cases where more than two homologues happen to be in close proximity.

These cells, however, exhibit fairly regular bivalent formation. This is because the members of each bivalent were sister chromatids before C mitosis. Thus these automatically became premeiotically associated in formations referred to as "pairs of skis" by Nebel and Ruttle⁸. Synapsis and chiasma formation then ensued.

Bivalents were formed by these chromosomes which were associated because of failure of anaphase movement, and so it can be concluded that colchicine does not inhibit synapsis or chiasma formation. Also it can be concluded that colchicine cannot disrupt chromosome association once it has taken place but can only inhibit such association from being initiated. This clearly shows that pre-

meiotic association and synapsis are two distinct phenomena.

Colchicine is unable to disrupt chromosome association, and so the absence of such association in the hexaploid cells in this study indicates that the chromosomes of these cells were not premeiotically associated when colchicine was applied. This, however, does not necessarily mean that chromosomes are only associated immediately before meiosis, for there may be an association-disassociation cycle operating. This would involve normal association of homologues with disruption to some degree when the chromosomes go through the processes of successive mitoses. Such behaviour has been suggested by Feldman, Mello-Sampayo and Sears¹⁰ following their detection of a vestige of chromosome association in mitotic cells of hexaploid wheat.

Effect of "Hardening" Radish Seeds

Subjecting seeds to one or more cycles of wetting and drying before sowing, in the process called "hardening", is said to affect the subsequent growth of plants in adverse environmental conditions. Various Russian workers, cited by May et al., have found that such treatment increases the resistance of plants to drought, heat and frost, but others2 have failed to confirm this. We have therefore grown radish plants from hardened and unhardened seeds, in wet and dry soil conditions at three levels of soil fertility, to find out whether hardening alters yields in different circumstances.

Radish seeds (Raphanus sativus L., variety 'Cherry Belle') were subjected to two cycles of wetting and drying, in which they were allowed to absorb water equivalent to about 25 per cent of their dry weight and then air-dried at about 72° F. A range of media, with increasing fertility and water-holding capacity, was compounded by mixing 1:2, 2:1 and 3:0 parts by weight of fertile clay loam and infertile grit, respectively. No fertilizer was added.

Twelve 5 in. plastic pots were filled with each mixture and sown with either treated or untreated seeds a week after the second hardening cycle. The emergent seedlings were thinned to one plant per pot. Within each group of six pots, three were kept moist by rewetting the soil to field capacity whenever 15 per cent of the available water had been lost, as shown by daily weighing, and three were not watered at all after an initial wetting to field capacity at the beginning of the experiment. The pots were housed in a growth room at about $68^{\circ} \pm 1^{\circ}$ F and a fluorescent light intensity of about 470 ft.-candles for 12 h daily.

In the moist soil, plants from hardened seeds grew better (Fig. 1) and produced significantly more dry weight than unhardened plants, irrespective of soil fertility, whereas there was no significant difference between hardened and unhardened plants in the dry regime except in the soil with the highest fertility and water-holding capacity.

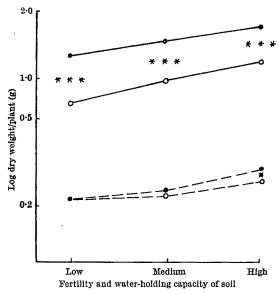

Fig. 1. Effects of seed treatments and soll moisture on growth of radish in three soll mixtures. \bullet — \bullet , Seeds hardened, moist soilwater regime; \bigcirc — \bigcirc , unhardened, moist; \bullet — \bullet — \bullet , hardened, dry; \bigcirc — \bullet — \bigcirc , unhardened, dry. \bullet , P=0.06; \bullet * \bullet *, P=0.001.

There was an increase in dry weight with increasing fertility of the mixture, irrespective of other treatments, but there were no striking interactions between any of the treatments. Similar trends were also shown for leaf areas, except that hardened plants in the least fertile mixture had significantly smaller leaf areas than unhardened plants in the more fertile soils.

These results suggest that, at least in some circumstances, "hardening" seeds may confer a greater advantage in favourable than in adverse growing conditions.

GENETICS

Haemoglobin Variant in a Bushman: Haemoglobin Dβ-Bushmanαβ₂₂ ^{16Giy→Arg}

VARIANTS of human haemoglobin A with an electrophoretic mobility identical with Hb-S at pH 8.6, but not causing sickling, are designated HbD. This type of haemoglobin has been found in many widely separated geographical localities. In six cases the haemoglobins D were structurally identical with the substitution glutamic acid→glutamine at position 121 of the β-chain^{2,3}. These samples were obtained from a Punjabi, a Caucasian from North Carolina, an Italian family living in Chicago, a Portuguese, a Greek Cypriot and a white family living in Los Angeles in whom Hb-S was also present.

Two other samples of HbD had different substitutions. One obtained from a Turkish Cypriot was an α -chain variant, and the other came from a Gujerati and had an amino-acid substitution in the region β 18-30 (ref. 4). In northwest India, HbD has been found in frequencies of up to 2 per cent (ref. 5), while only sporadic cases of HbD have been reported from the African Continent^{6,7}.

HbD Ibadan found in a member of the Yoruba tribe has recently been shown to possess lysine in place of threonine at position 87 of the β chain (ref. 7). T. Jenkins et al. (unpublished work) found an HbD in a Kgalagadi (Bantu) schoolboy living at Kang in the Kalahari desert of Botswana (formerly the Bechuanaland Protectorate).

This article describes the amino-acid change in another example of HbD, which was found by one of us (T. J.) in a Kalahari Bushman family resident in the Ghanzi district of Botswana. The variant haemoglobin occurs together with normal adult haemoglobin in a 30 yr old man, his mother and all three of his children.

In the five individuals it was found, by starch block electrophoresis, to account for 34 per cent, 36 per cent, 37 per cent, 38 per cent and 39 per cent of the total haemoglobin. Tests for sickling were negative and the reduced form of the variant haemoglobin was completely soluble in 2·24 molar phosphate buffer, pH 6·9. Haemoglobin concentrations of individuals with the variant haemoglobin were slightly below normal limits (11–13 g/100 ml.), the packed cell volumes were within normal limits; thin blood films showed slight hypochromia and some degree of anisocytosis as well as some target cells.

No abnormal HbA_2 component was evident on electrophoresis, suggesting that the amino-acid substitution was in the β -chain. Hybridization experiments, using human haemoglobin variants of known chain abnormality (HbS and $HbJ\alpha$ Cape Town⁸) and with canine haemoglobin, confirmed that the substitution was in the β -chain in this sample of HbD.

A sample of freshly drawn red cells from one member of the family was sent to London, where further analysis showed that this abnormal haemoglobin was caused by a previously undescribed amino-acid replacement and it is therefore called HbDβ-Bushman.

The haemoglobin was purified by starch block electrophoresis using 0.05 molar barbiturate buffer, pH 8.6. After elution and concentration, further electrophoresis on starch block with 0.04 molar sodium phosphate buffer, pH 7.0, yielded pure HbDβ-Bushman. Globin was prepared from the pure haemoglobin and digested with trypsin. The soluble peptides of the tryptic digest were subjected to paper electrophoresis in pyridine, acetic acid and water (10:0.4:90) buffer, pH 6.4, followed by chromatography in pyridine, isoamyl alcohol and water (35:35:27). The peptides were located with 0.2 per cent ninhydrin and specific staining for tryptophan and arginine was carried out.

The following differences between the fingerprints of $HbD\beta$ -Bushman and HbA were visible (Fig. 1). (a) Peptide β T2, which stains positively for tryptophan, was absent in the $HbD\beta$ -Bushman fingerprint. (b) An additional peptide with similar electrophoretic mobility to β T2, but with slightly greater chromatographic mobility,

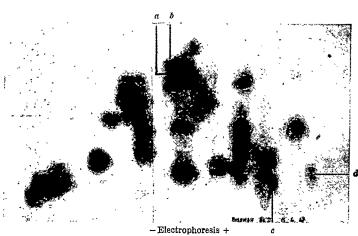

Fig. 1. Fingerprint of HbDβ-Bushman.

was present. It stained positively for tryptophan and arginine. (c) An extra basic peptide positive for arginine was visible. (d) β T3, positive for arginine, was reduced in amount.

These results can be accounted for if β 16 Gly has been replaced by β 16 Arg in the Bushman haemoglobin. The amino-acid sequence of HbA and HbD β -Bushman in this region would be as follows

In HbD β -Bushman a tryptic split would occur after Arg 16, giving rise to a peptide consisting of residues 9–16, positive for tryptophan and arginine, and having the same net charge as β T2 of HbA. The observed peptide spot 2 could be such a peptide. β T3 in HbD β -Bushman and HbA would consist of residues 18–30. In addition, a peptide comprising residues 17–30 might be expected in HbD β -Bushman, resulting from incomplete tryptic cleavage of N terminal lysine of this peptide. The position of the observed spot 3 in the Bushman fingerprint is that expected for Lys- β T3 (residues 17–30). The presence of this peptide would explain why β T3 (residues 18–30) is reduced in amount in the fingerprint of HbD β -Bushman.

	Tabl	e 1	
	Peptide 2, molar ratio		Peptide 3, molar ratio
Thr Ser Ala Val Leu Try Arg	1·0 0·7 2·2 1·1 1·1 + 1·0	Asp Glu Gly Ala Val Leu Lys Arg	2·2 2·7 0·8 3·0 1·1 1·1

Tryptophan was detected by Ehrlich's reagent and assumed to be one residue. The figures for peptide 2 have been corrected for a small amount of α T5 impurity. From the electrophoretic mobility of peptide 3, one of the aspartic acid residues must have been present as asparagine. The figures for peptide 3 have been corrected for a small amount of α T4 impurity.

Amino-acid analyses of peptides 2 and 3 are consistent with this conclusion. These two peptides of the HbD β -Bushman were eluted from a heavily loaded fingerprint, stained with 0.02 per cent ninhydrin. The peptides were hydrolysed with 6.7 normal hydrochloric acid at 110° C for 18 h and subjected to amino-acid analysis (Table 1).

Peptide 2 when compared with β T2 has one extra arginine residue, one less glycine residue and one less lysine. This confirms that β 16 Gly has been replaced by Arg in HbD β -Bushman, and that peptide 2 comprises residues 9–16. In addition, the amino-acid composition of peptide 3 is that expected of Lys- β T3.

The results of the fingerprinting of the HbD β -Bushman and the amino-acid analysis are therefore consistent with the haemoglobin being $\alpha_2\beta_2$ 16Gly \rightarrow Arg.

The fingerprint prepared from the haemoglobin variant HbD β found in a Gujerati, described by Benzer *et al.*⁴, also shows reduced yield of the peptide β T3, suggesting this haemoglobin is similar to the one described here; however, in the former a new peptide was located in the neutral region of the peptide map, while no such peptide was present in our case.

It is interesting that the analogous substitution has been found in the δ chain, in the variant Hb-B₂ (α₂-δ₂16Gly-Arg (refs. 10 and 11)). The fingerprints obtained from HbD-Bushman and HbB₂ are similar. In the HbB₂, a peptide comprising residues 9-17 was observed because of incomplete tryptic splitting after Arg 16 (ref. 11). This was not observed in the Bushman fingerprint, presumably because complete hydrolysis had occurred after Arg

The amino-acid β 16 has been shown to be in the A helix of haemoglobin (residue A 13) lying near the surface of the haemoglobin molecule^{12,13}. This position is known to be tolerant to substitution, because it is occupied by acidic, neutral or basic amino-acids (but not arginine) in various normal haemoglobins and myoglobins¹³. The substitution of arginine in this position would therefore not be expected to give rise to gross haematological abnormality. Further work is necessary before the mild haematological changes found in the carriers of this haemoglobin can be definitely related to its presence.

We thank Professor N. A. Barnicot for his advice.

Blood Groups in Natives of Easter Island

CONSIDERING their geographic location, the islands of the Pacific Ocean should have been inhabited first by Asiatic and/or American peoples. Heyerdahl¹ showed that this is a possibility when he sailed from the Peruvian coasts

to the Polynesian Islands by a very primitive means, Because of the proximity of the islands to America, determination of the blood groups of the inhabitants should clarify the situation. Until Graydon and Simmons' study² of blood samples of pure natives obtained by Heyerdahl, only the classical groups were known³⁻⁷.

Easter Island (Pascua, Rapa-Nui), to which we sailed in 1963 on the Transporte Aka-Pinto of the Chilean Army, is a small volcanic island in the Pacific Ocean, 182 km², located off the Chilean coast, 2,040 miles from Valparaiso and 2,300 miles from Tahiti (see Fig. 1). It has 1,170 inhabitants, in 200 families who are very much mixed with Polynesians, Europeans and Chileans. There are only sixty pure natives, who believe they are descended from the Polynesian King Hotu-Matua⁸.

Our subjects were 233 natives of which 137 were men and 96 were women. Fifty of them were children and only 35 were pure natives. Blood specimens were taken, from a vein, in acid citrate dextrose and blood groups were determined on the island, except in the case of a few Easter Islanders, whose blood was determined on board ship. Determination of the haptoglobins and abnormal haemoglobins was carried out on the mainland. Techniques used were standard ones. Sera were given by Ortho except for the anti Dia that was sent by Layrisse from Venezuela.

In the general population there is a high frequency of A (66 per cent, gene frequency 0.42), and A₁ is in 92 per cent of the population. N and s predominate on M and S, respectively, with s usually related to N. There is a high frequency of R2(cDE) and absence of Kell and Dia; a low frequency of Fya (40.3 per cent) and an extraneous mixture index of 8 per cent for A2, 2.5 per cent for B and 0.5 per cent for dd, and there is a large proportion of Ro (cDE). For 35 "pure natives" the results agree with those of Graydon and Simmons². B is absent, as in the general population, and in comparison, gene O is more frequent (0.61 versus 0.54) in the pure natives as are genes M (0.48 versus 0.39), R2 ($cD\bar{E}$) (45.71 per cent versus 24.63 per cent) and Fy^a (0.53 versus 0.23). R^o (cDe) is absent from the "pure natives", compared with its presence in 6.16 per cent of the general population.

The inhabitants of Easter Island have been identified both physically and genetically with the rest of the Polynesians¹⁰, but the origin of the primitive inhabitants of the island is unknown. The islands were possibly then, as they are now, a meeting place of routes to Micronesia, Indonesia and Polynesia in the west and America in the east. The genetic factors which the islanders have in common with the American Indians suggest that these were the primitive inhabitants of Easter Island. They lack B, AB and dd, and have a high percentage of R2 (cDE)

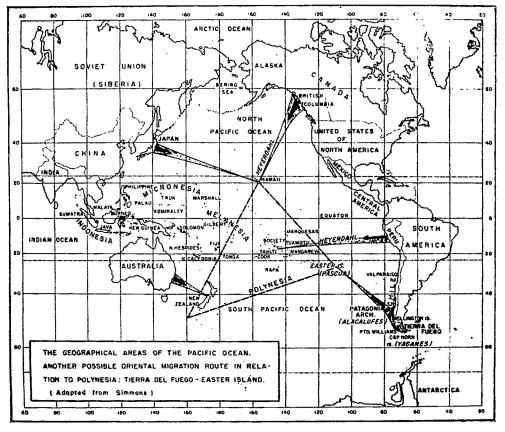

Fig. 1

Fya and s. Easter Islanders are mostly A and N and pure Indians have only O with the gene M predominating. Factor Dia is absent in Polynesians, but is found in all Indians to a greater or lesser extent, except in the Fuegians¹¹. There is possibly a greater genetic relationship between these Indians and the pure natives of Easter Island, particularly the Alacalufes or "sea nomads" who live in the Archipelago of Occidental Patagonia (Fig. 1), the closest to Easter Island. They could have brought in the genes O, M, R2 (cDE) and Fya which are also very frequent in the pure islanders who also lack chromosome R^{0} (cDe). The Yaganes, on the other hand, have a larger proportion of R_{1} (CDe), R^{0} (cDe) and N, but these last two genes could come from a mixing with Europeans that was revealed when B, A2 and a possible case of glucose-6-phosphate dehydrogenase deficiency were found.

The present inhabitants of Easter Island might also have been a mixture of so-called "pure" or primitive with other tribes from North America (British Columbia) as Heyerdahl suggested. Possibly these were the ancestors of the present Blackfeet and Bloods, who contributed the gene A, the percentage of which is actually the highest in the world13. Peruvian incursion towards the end of the last century, migrations and epidemic diseases have much reduced the population. This, and mixing with Europeans, Chileans and Polynesians (the absence of haemoglobin S excludes mixing with Negroes), makes identification of the present population with the primitive inhabitants of Easter Island very difficult.

IMMUNOLOGY

Antibodies to IgM in Normal Human Sera

THE sera of some normal human subjects contain antibodies to human IgG1, and have proved useful in investigating the genetic markers of human IgG (the Gm and Inv factors). But the IgM proteins of different human sera have also been found to differ serologically2, and investigations by means of precipitin systems have led to the designation of possible subclasses3,4. set out to determine whether normal human sera contain antibodies to human IgM, for such reagents might help the delineation of the structure of the immunoglobulin. We have screened more than two thousand normal human sera for antibodies to IgM; forty-two were found to have such activity.

Table 1. AGGLUTINATORS IN NORMAL SERUM FOR WALDENSTRÖM'S MACRO-

MINDON	CONTEND ON HOR	WAN DIE	TIMOOTIE
4 47	No. of sera		tive sera
Antigen	screened	No.	Per cent

\mathbf{Pr}	437	$\frac{4}{2}$	0.2
Ka	302	2	0.7
Au	140	0	0.0
Gi	29	0	0.0

For use in the screening procedure, IgM proteins from twelve patients with Waldenström's macroglobulinaemia were isolated by either euglobulin precipitation or starch block electrophoresis, depending on the physical characteristics of the individual protein. The euglobulin precipitations were repeated three to five times, and the precipitate was washed extensively with distilled water after the first and last precipitation. All preparations were then chromatographed on a column of 'Sephadex G-200' to remove remaining contaminants. The purity of each preparation was checked with appropriate antisera by both immunoelectrophoresis and gel double diffusion in agar. Each of the twelve proteins was then coated on type O Rh-positive red cells with the use of trivalent metal ions^{5,6}. Sera to be tested for antibodies to IgM were obtained from routine blood donors.

For antibody testing, one drop of serum was added to one drop of a 2 per cent suspension of cells on a glass tile at room temperature. The tile was gently agitated for 2–5 min and read for agglutination. Saline solution and sera known to contain no IgM agglutinators served as negative controls, and rabbit anti-IgM antiserum monospecific for IgM was used as a positive control to ensure that the cells were coated. Cells coated with human serum albumin were used as cell controls. Simultaneous screening for IgG agglutinators was carried out with human IgG and anti-D (Ripley) coated cells.

For inhibition experiments, one drop of an appropriate dilution of agglutinator was incubated with serial dilutions of inhibitor for 15 min at room temperature. The cells were then added and agglutination was tested as in the screening procedure. Sera with agglutinator activity were chromatographed on a column of 'Sephadex G-200', 2.5×100 cm, in 0.17 molar tris saline buffer, pH 8. A sample (1 ml.) of serum was applied to the column; fractions (3 ml.) were collected, and the protein content was estimated by determining the absorbancy at E_{280} m μ with a Zeiss PQ II spectrophotometer. Selected fractions were then tested for haemagglutinating activity.

Macroglobulin antibody-antigen complexes were prepared by incubating a mixture of a known saline anti-Rhoserum (1:1) with Rh-positive cells for 2 h at 37° C. The cells were then washed three times with saline. Samples, 0.5 ml., of the packed washed cells were incubated with 0.1 ml. of agglutinator serum at room temperature and at 37° C for 30 and 60 min and were then centrifuged. A sample (0.05 ml.) of the supernatant fluid was removed and tested for agglutinating activity. The remaining mixture was incubated overnight at 4° C and similarly tested. A further sample of sensitized cells was lysed in distilled water and washed three times or until the supernatant fluid was clear. The stroma was incubated with the agglutinator at 37° C for 1 h and then centrifuged; a portion of the supernatant was removed and tested for agglutinating activity. The rest of the mixture was incubated overnight at 4° C, and was then similarly tested.

The number of sera which were screened for anti-IgM antibodies and the number positive with each of the twelve coats are listed in Table 1. It can be seen that the number of sera positive against each coat varied from none to 8.3 per cent. The two highest percentages (5.3 per cent for coat Pi and 8.3 per cent for coat Bi)

may reflect the fact that fewer sera (50 and 55, respectively) were screened against these antigens. Only one of the agglutinators had a titre greater than 1:2; serum Fe had a titre of 1:32 against the Ca coat. Two sera had activity against both IgG and IgM. Two other sera reacted with more than one IgM coat; both of these were active against both Bi and Ca. All the other agglutinators reacted with only one coat of the panel.

Five agglutinators to Ca, including serum Fe, were selected for further study. Four reacted with cells coated with isolated Ca heavy chain in titres equal to those obtained with cells coated with the whole molecule. To determine whether the agglutinators of the various coats could be used for defining genetic variations in IgM molecules, the inhibition of these sera by the twelve isolated macroglobulins was tested at protein concentrations ranging from 0.0025 mg to 1 mg/ml. In each case, only the homologous paraprotein produced inhibition. Of seventy-two normal sera screened for their ability to inhibit the agglutination reaction with Ca and Bi coats, only two (2.8 per cent) inhibited agglutination of the Ca coat, and only three (4.2 per cent) the Bi coat. The inhibiting property was lost when the serum dilution was greater than 1:2. Again, the inhibitors appeared to be specific for the homologous coat.

The agglutinator of serum Fe was characterized by fractionation on a column of 'Sephadex G-200'. The fractions obtained were immediately tested for agglutinating ability. As shown in Fig. 1, the material from the 19S peak agglutinates IgM-coated cells, whereas the protein from the 7S and 4S peaks does not. The agglutinator proved to be labile, and concentration procedures were sufficient to destroy the activity. Dialysis of serum Fe against 0·1 molar mercaptoethanol overnight at 4° C, with subsequent removal of the reducing agent, destroyed the activity. Serum Fe dialysed at 4° C without reducing agent retained activity. The reduced serum, however, blocked the agglutination of untreated Fe.

In view of the limited specificity of these sera, the possibility that they could represent anti-antibodies was explored. Rh-positive cells heavily coated with anti-Rh saline agglutinin were incubated with an agglutinator serum at room temperature and at 37° C for 60 min and overnight at 4° C. Stroma from sensitized cells were used in similar experiments. In all instances, these attempts at absorption failed to remove the agglutinating activity.

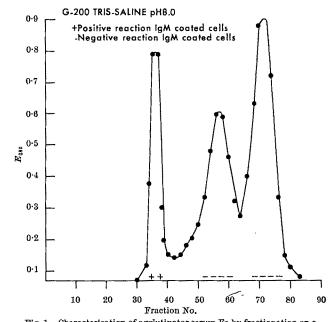

Fig. 1. Characterization of agglutinator serum Fe by fractionation on a 'Sephadex G-200' column. The agglutinator was present only in the 19S peak.

Thus these anti-IgM agglutinators do not seem to be antiantibodies to IgM.

Normal sera have long been known to contain antibodies to various antigenic determinants on the IgG molecule1. The agglutinators described here are distinguished by their low incidence and very low titre. They are remarkable in that their specificity seems to be limited to the IgM coat used for their detection. The specificity in all instances seemed to be directed primarily towards the heavy chain of IgM, as shown by the direct reaction with isolated heavy (µ) chain and the failure to react with red cells coated with IgG or light chains. At present, the most plausible explanation for the restricted activity seems to be configurational changes in the molecule produced during binding to the red cell by the metallic ions. Individual macroglobulins vary in amino-acid composition7 and the heavy chains of the immunoglobulins are probably divided structurally into a variable and an invariable region, as has been shown for the light chains, and so it seems possible that the variable regions contain antigens available for reaction. The low percentage of normal sera capable of inhibiting such reactions suggests that the reagents used in this investigation are of limited value for detecting genetic antigens of macroglobulins. It is possible, however, that the antigen(s) involved represents uncommon determinants. Further work is required to elucidate this point.

The possibility that these agglutinators are anti-antibodies seems to be remote for two reasons. First, they were blocked by reaction with free homologous antigen, and second, macroglobulin antibody-antigen complexes failed to remove agglutinator activity. second point, however, can be disputed in the light of recent reports that at least some human anti-antibodies have Gm specificity. The nature of the agglutinator is interesting, because it seems to be a macroglobulin. It is present in the first peak obtained by 'Sephadex G-200' chromatography and is sensitive to mercaptoethanol. Neither of these criteria is absolute inasmuch as polymer IgG molecules and monomer IgM molecules Unfortunately, absorption by antisera to IgM is not possible because such sera themselves in high dilutions ($\hat{1}:100,000$) agglutinate the test cells.

In summary, we have established the presence of agglutinators for IgM in human sera. They seem to be macroglobulin molecules and to have limited specificity. The question of IgM genetic determinants remains unanswered.

Mixed Agglutination between Established Burkitt Cell Lines and Fresh Biopsy Specimens

When the serum from patients with Burkitt-type lymphoma is incubated with living suspensions consisting mostly of Burkitt tumour cells, the cell surfaces become coated with immunoglobulin as detected by the fluorescent antibody technique¹. Evidence suggests that this surface reaction is correlated with the occurrence of a virus like particle, and that this particle is also associated with a cytoplasmic antigen detected by the fluorescent antibody technique2, but there are good reasons to distinguish between this and the membrane fluorescence phenomenon demonstrable on the living cell.

A working hypothesis has been that the gamma globulin factor which combines with this cell surface may be antibody to a tumour specific antigen, analogous to that found in certain murine lymphoma systems. While testing this hypothesis it became important to compare surface antigens on living fresh biopsy cells and those on the established culture cell lines.

The finding that a biopsy specimen from a 17 yr old patient with Burkitt lymphoma was heavily coated with gamma-M immunoglobulin provided the experimental approach. If this immunoglobulin coating were antibody against a surface antigen present on the lymphoma cell (but not the normal spleen cells of the patient), sufficient free antibody combining sites should exist to co-agglutinate with uncoated cells bearing free surface determinants of the same specificity. This proved to be so, for when these biopsy cells were mixed with a long-established line of Burkitt cells, giving the membrane fluorescent reaction, mixed agglutination was observed.

The technique employed was as follows: one of the cell lines to be examined, usually the cultured cell line, was incubated in 0.025 molar fluorescein diacetate in balanced salt solution (BSS) for 20 min at room temperature, as described before³. These cells showed intense cytoplasmic fluorescence in ultraviolet or blue light because of splitting of the compound in the living cell. Fluorescence was sustained as long as the cell lived. After incubation the cells were washed twice with BSS and then mixed with the second type of cell to be examined. Some (0.1 ml.) of the fluorescent cells in a concentration of approximately 5×10^5 /ml. were mixed in a 1·0 ml. plastic tube with 0·1 ml. of the second cell type, usually a biopsy cells uspension at a concentration of 1×10^6 cells/ml. A favourable ratio of fluorescent cultured line cells to biopsy cells seemed to be between 1:5 and 1:10. This mixture was sealed and incubated at 37° C for 30-45 min. A small drop containing gravity sedimented cells was taken from the bottom of the tube with a small bore Pasteur pipette, put on a glass slide and covered with a glass cover. The mixed cells were examined with a dark field condenser, orange tungsten light and ultraviolet light mixed in an orthoplan microscope (×540). In these preparations, the biopsy cells without fluorescein were orange and usually small (8–11 μ in diameter). The cultured lines were seen as uniformly fluorescent and large (14–18 μ in diameter).

It was extremely important to perform each test with as near 100 per cent living cultured line cells marked with fluorescein as possible, because it proved unreliable to attempt to distinguish the cultured line from the biopsy cells entirely on the basis of size. The presence of a significant number of nonliving and therefore nonfluorescent cultured cells gave irregular results. Agglutination of the cells was scored for 200 single cells; never clumps. A fluorescent cell was considered positive when one or more nonfluorescent, usually smaller, cells adhered to the surface of the single fluorescent cell. No systematic attempt was made to grade the agglutination between single cell adherence and complete rosette formation; the average number of adherent cells in a positive test was usually

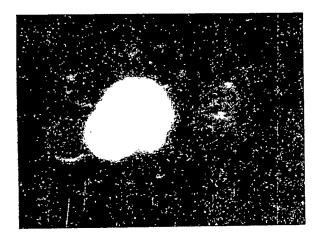

Fig. 1.

between two and five. In an attempt to block the test, a gamma-G globulin preparation from a Burkitt serum known to produce membrane fluorescence when incubated with the same cultured cell line4 was incubated for 20 to 30 min at room temperature before incubation with the second cell line, and washed twice in BSS before the mixture was made. Fig. 1 shows a positive cultured line cell with a rosette of smaller biopsy cells around it.

This test has been performed on four different biopsy specimens of African origin. Dau and Mar were from patients with histologically confirmed Burkitt lymphoma. Phy was taken from a patient with a lymphosarcoma of less distinctive histology. Ngi biopsy specimen was from a haemangiopericytoma of the mandible. The cultured cell lines Jijoye (HR-5), EB-3, Annah and B35M show The lines a positive membrane fluorescence reaction. Ogun and Kudi show no membrane fluorescence.

Preliminary data are presented in Table 1, and show that mixed cell agglutination occurred between the

heavily \(\gamma M\)-coated biopsy specimen of Dau and Jijoye. The lightly YG immunoglobulin-coated biopsy cells of Phy and Mar reacted to a lesser extent with Jijoye. Ngi, which had no detectable antibody coat, did not react with Jijoye. Thus those cell lines showing strong membrane fluorescence reactions when exposed to positive Burkitt lymphoma sera were the only ones which agglutinated with the coated biopsy cells. The biopsy cells with no immunoglobulin coating failed to react with the same cell lines. Furthermore, the reaction was blocked by preincubation of the Jijoye cell line with the vG fraction from a patient with Burkitt lymphoma. It seems reasonable to assume that the antigen like properties of the biopsy and the cultured cell surfaces are identical.

This preliminary observation is presented at this time in order to make possible more extensive examination of this reaction and with a larger number of biopsy cell types. If this observation is confirmed by examination of additional biopsy specimens, and the surface property is identified as a true antigen, the technique may make possible studies of the antigenic surface mosaic of individual tumours, of the specificity of the serum factor, and of the relationship between various tumours of differing

host and geographical origin.

CYTOLOGY

Effect of Phytohaemagglutinin on the Surface Charge of Human and Murine Lymphocytes

Non-immune murine lymphocytes are cytotoxic to allogeneic target cells in the presence of phytohaemagglutinin (PHA)¹. In a similar system using cells of human origin this "allogeneic inhibition" occurs without PHA (ref. 2). The role of PHA in the mouse experiments is unknown. but it has been suggested that it acts by promoting intercellular contact, thus permitting the close apposition of dissimilar groups of histocompatibility antigens3. This would imply that there is some factor in the mouse experiments which tends to inhibit close intercellular contact but which does not operate in experiments using human cells.

A recent communication⁴ has suggested that cell surface charge effects may modify certain interactions between lymphocytes and target cells. The magnitude of potential

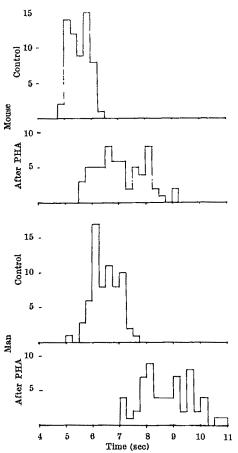

Fig. 1. Frequency distribution of electrophoretic mobilities of murine and human lymphoid cells before and after exposure to PHA, expressed as time taken to travel 31.6μ . The distribution is plotted as "number of observations" with a class interval of 0.25 sec.

energy barriers to contact between these cells may well be regulated by the sum of charges at their cell peri-Experiments were therefore carried out to compare the surface charges of human and murine lymphoid cells and to assess the effects of treatment with PHA. Normal human lymphocytes were obtained from the peripheral venous blood of adult volunteers by the method of Coulson and Chalmers. The resulting cell suspensions were treated with hypotonic saline for 30 sec to lyse red cell contaminants and the suspensions were left to stand for 1 h at 37° C to allow granulocytes to adhere to the walls of the vessel. The preparations obtained by this method contained at least 97 per cent lymphocytes, less than 5 per cent of which failed to exclude lissamine green.

Mouse lymphoid cells were obtained from the minced and filtered spleens of adult CBA inbred mice. These cells were treated in the same way as human lymphocytes and contained at least 95 per cent lymphoid cells with about 85 per cent viability.

Each suspension was diluted in medium 199 to a final concentration of one million cells/ml. and to 1 ml. of each preparation was added 0.1 ml. of reconstituted PHA (Burroughs Wellcome). Both treated and untreated suspensions were incubated for 30 min at 37° C. After incubation the cells were washed and resuspended in 0.145 molar aqueous sodium chloride adjusted to pH 7.4with 0.145 molar sodium hydroxide.

Electrophoretic mobilities were measured in a cylindrical micro-electrophoresis apparatus described by Bangham et al.⁵. The cells were timed over a distance of 31.6μ at 25° C. Sixty observations were made on each preparation and the results from each batch compared by means of Student's t test. The results were also plotted as a fre-

quency distribution histogram with a class interval of 0.25 sec and are shown in Fig. 1.

These results indicate that CBA mouse spleen cells have a higher electrophoretic mobility than human lymphocytes (0.05 < P < 0.1) and that treatment with PHA reduces their mobility (P < 0.05). The mobility of normal human lymphocytes is also substantially reduced by PHA (P < 0.001). Comparison between mouse lymphoid cells treated with PHA and control human cells reveals no significant difference (P > 0.2).

Electrophoretic mobility is largely a measure of net surface charge,, so it is concluded that mouse lymphoid cells bear a higher net negative charge than human peripheral blood lymphocytes and that PHA abolishes this difference. This effect could provide a mechanism for the facilitation of allogeneic inhibition by PHA. Treatment of murine lymphoid cells with PHA, by reducing their high surface charge, would diminish electrostatic intercellular repulsion to levels which permit direct contact between cell walls exhibiting dissimilar antigenic groupings. Human lymphocytes, with their lower surface charge, would make contact with target cells more readily, thus dispensing with the need for PHA. Sundaram et al.8 have revealed that lymphoid cells stimulated with antigen have a reduced electrophoretic mobility which is further reduced by incubation with the same antigen. This would explain the pronounced cytotoxic effects of immune mouse lymphoid cells on target cells in the absence of PHA (ref. 9). The failure to demonstrate allogeneic inhibition recently reported by Chernyakhovskaya et al. 10 is at variance with previous reports by Hellström and may be explained by the omission of PHA from their culture system.

The mode of action of PHA as a potent mitogen is poorly understood. It is antigenic¹¹ but there is no evidence that its mitogenic effect is related to its antigenicity. Similarly, the relationship between an antigenic molecule and its appropriate lymphoid cell receptor remains a subject for speculation. An analysis of the effects of PHA and antigen on the physico-chemical properties of the lymphocyte cell wall should provide a better understanding of immune mechanisms at the cellular level.

Cell Division after Removal of the Division Line in Stentor

Can a cell which has already entered on division go on to divide even when the presumptive or visible fission line or furrow is removed? This question can be answered conclusively for the large ciliate Stentor coeruleus, which is remarkably suitable for micro-surgical operations. One might expect that the ciliate would then be unable to divide. Uhlig² reported this finding after deleting the fission line from dividing S. coeruleus, and when Suzuki³ excised mid-cell disks bearing the visible fission line from dividing Blepharisma, these ciliates also failed to divide, although removal of the presumptive fission line did not prevent division, as I have confirmed in Stentor.

To obtain abundant dividers, older static cultures of Stentor were supplied with ample Paramecium bursaria and divisions occurred on the following day. Stentors entering on division can be identified as early as 6 h before furrowing by the presence on one side of the cell of an oral primordium, as shown in Fig. 1a. This produces the new feeding organelles for the eventual posterior daughter cell, also indicated in Fig. 1a.

The principal variable in the experiments was the stage at which the presumptive or manifest division line was removed. The later the stage at which the cells could still divide, the more significant, for deletions at early stages might allow time for reconstruction of some hypothetical divi-

sion organelle or constriction ring. Evidently the locus of the fission line is pre-established or determined at an early stage. Excision of the anterior ends of the dividers even 5 h before furrowing resulted in unequal division yielding small anterior daughters and the cells divided where they would have done, had they not been out (unpublished results). Thus the presumptive division line can be removed by deleting mid-cell parts.

Progression toward fission has been staged by clearly recognizable steps in the development of the oral primordium1. When this development is arrested, the appearance of the fission line and furrowing is correspondingly delayed, and if the primordium regresses division is cancelled4. Up to stage 6 of primordium development the division line may be called presumptive for it is not visible. During stage 6 formation of the new set of feeding organelles is essentially completed; the micronuclei divide and the macronucleus is compacted into a single mass from a chain of nodes. There is no indication that division of either type of nucleus triggers or participates in cytokinesis; rather, the cytoplasm signals the nuclear behaviour1,5. A Stentor can be enucleated as early as stage 6 without preventing either division or final oral differentiation for the posterior daughter cell1.

In late stage 5 and early stage 6 the incipient furrow is first indicated by a line of colour contrast around the equator of the cell produced by predivision of the opaque, underlying, glycogenoid carbohydrate reserve granules. Where this line intersects the longitudinal pigment bands the blue-green pigment granules are displaced in late stage 6, leaving a colourless, visible division line. It may be inferred from silver staining studies on other ciliates, as described by Fauré-Fremiet, that the ciliary rows or kineties lying between the bands are also severed along this line. Furrowing in the division line then begins, first on each side of the anterior end of the oral primordium, to cut this anlage into the posterior daughter cell, and then extends right and left around the equator. Gathering and bunching of the cut ends of the pigment bands clearly indicate that fission is an active constriction of the cell cortex sharply at the fission line.

Selected dividers were quieted in methyl cellulose solution and operated on by a hand-held glass needle¹. Transection of the cell on each side of the equator isolated a mid-cell fragment, initially disk-shaped, carrying almost all of the prospective or visible fission line or furrow except for its forward bend around the oral primordium. This

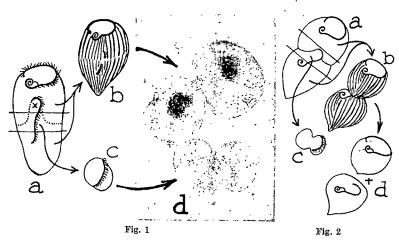

Fig. 1. Operation on a stage 4 divider and consequences. (a) Two cuts on each side of the presumptive division line (dotted) isolated into a middle fragment (c) almost all this locus except the part running forward to include the anterior end of the lateral oral primordium (x). (b) The two remaining major portions of the cell were fused together with a line of heal indicated by breaks in the pigment bands. (d) Both fragment and cell remainder divided, yielding four daughter cells.

Fig. 2. Same as Fig. 1 for a late stage 6 divider beginning to furrow. (a) All the furrow was excised into a fragment which constricted only half way (c). (b) In 30 min the cell remainder formed a new furrow and constricted half way, and after 45 min the cell pinched in two and daughter cells were separated.

can be seen in Fig. 1a. These pieces were observed to determine whether they could divide. To test the remainders—cell minus fission line—for division, the anterior had to be healed to the posterior part. This fusion frequently required sacrificing the mid-piece which had to be cut initially and distorted to bring the two other parts together before it was excised.

One positive case is sufficient to demonstrate what the Stentor cell can do. Figure 1 shows how a late stage 4 divider was cut and that 2 h later both the middle piece carrying the presumptive fission line and the cell remainder pinched in two as in normal division, each producing two separate daughter cells. Another case of the same operation performed on a divider in late stage 6 after furrowing had begun is shown in the protocol sketches of Fig. 2. Although the furrow was removed, the cell nevertheless formed a new furrow in the line of heal and divided promptly into two separated daughter cells. The midpiece carrying the original furrow constricted only half way and therefore did not yield daughter cells.

The presumptive or manifest division line or furrow was successfully removed from fifty dividers at stage 4 to 7 inclusive. In eight instances all of the equatorial disk was removed except for the oral primordium, which was left intact as a connexion between the anterior and posterior portions of the cell to assure their healing together. In twenty-one cases the anterior end of the primordium where the fission line begins was also excised or cut into the middle fragment to test whether the presence of this "initiator" region, shown in Fig. 1, is necessary for constriction after removal of the greater part of the division line. It was found to be unnecessary; the division line simply began in another place, and this is in accord with an earlier study.

We deleted the prospective or manifest fission line or furrow and graded the behaviour of fifty cells which continued to divide. The most complete performance, exemplified by the illustrated cases, consisted of full constriction in the line of heal and separation of two daughter cells. This form of division occurred in five Stentors with deletions made, one at stage 4, one at stage 5, and two at stage 6 with furrows, respectively, as shown in Figs. 1 and 2. Next was division without separation, in which constriction in the line of heal was complete and the cells all but separated yet remained attached and then melded back into one cell as the constriction relaxed. This occurred in the case of one cell

operated on at stage 4 and in seven cells cut at stage 6, two of which had begun furrowing. In twenty-seven cases with deletion of the original division locus at stages 4 to 7, the specimens showed definite, but partial, constriction. They were pinched in two up to half way, but the daughter cells remained joined by a wide stalk. Finally, in seven instances of cells operated on at stages 5 to 7, there was no apparent constriction when the time for fission arrived nor thereafter. Considering that the operation involved major deletion and injury, the performance of the specimens in cytokinesis after excision of the division locus, fission line or furrow was remarkable.

The twenty-eight middle pieces which carried the original presumptive or visible division line or furrow, and the fate of which was followed, showed the same grades of performance. In these fragments, in contrast to the cell remainders, the earlier they were cut the more significant. Ten went on to divide and separated tiny daughter cells, including one from a stage 4 divider as in Fig. 1c and two from stage 5 dividers which could go on to produce a visible division line and furrow within the isolated fragment. Four divided without separating daughter cells, twelve showed incomplete constriction, and two gave no indication of constrictive division.

These results seem to present new possibilities for a theory of cytokinesis. Current hypotheses derived from studies on egg cleavage, do not apply to Stentor and other ciliates. Because the macronucleus divides amitotically and the micronuclei endomitotically, there are no dominating mitotic spindle or asters to play an important part in the cytokinesis. Successful fission in equatorial Stentor fragments seems to exclude the cortical expansion hypothesis of furrowing; if anything, the cortex should be pulling away from the furrow in healing over the two extensive wound surfaces of a central disk fragment, yet complete furrowing can occur. It is highly improbable that the furrow in Stentor is an inward growing partition, because cells could refurrow and fully constrict only 45 min after the original furrow was excised, as seen in Fig. 2, and in cells relaxed or deconstricted after division without separation of daughters there is no indication of new cortical growth.

The normal division locus has been presumed to be a temporary differentiation gradually prepared for constriction, which is then indispensable for division. After the prospective or visible fission line or furrow is removed, however, other parts and perhaps any level of the Stentor cell can constrict transversely when the time comes for fission.

Staining of Mast Cell Acid Glycosaminoglycans in Ultrathin Sections by Ruthenium Red

STUDIES from our laboratories have shown that ruthenium red, empirical formula $[Ru_3O_2(NH_3)_{14}]Cl_6\cdot 4H_2O$, M.W. 858.5 (ref. 1), reacts specifically with mast cell granules2. These organelles are stained red and rendered electron dense, probably as a consequence of a reaction between the stain and granule acid glycosaminoglycan2. After vital staining or staining at fixation, the electron density is usually intense but irregular and sometimes varies from one experiment to another. The variation might be caused by differences in the content of glycosaminoglycan, blocking substances or poor penetration of the stain3. With vital staining it is also obvious that ruthenium red can function as a poly-cation histamine releaser, although at temperatures greater than $4^{\circ}\,\mathrm{C}$ this stain did not degranulate mast cells as markedly as did astra blau, a copper containing polyammonium

Most of the difficulties of staining glycosaminoglycans with ruthenium red for electron microscopy would be eliminated if ultrathin sections could be stained. Staining material embedded in epoxy resin did not increase appreciably the electron density of mast cell granules. but staining specimens embedded in the water-soluble glycol methacrylate (GMA, ref. 4) (Röhm and Haas, Darmstadt) was useful.

Peritoneal mast cells were collected from rats³, and fixed for 1 h in 4 per cent methanol-free formaldehydes or glutaraldehyde in 0·1 molar cacodylate buffer, pH 7·4, with or without 0.001 molar p-chloromercuribenzoates (Sigma Co., St. Louis, USA). Dehydration and embedding in GMA were carried out as described in refs. 7 and 8.

Sections 1µ thick were stained with 0.001 molar ruthenium red in 0·1 molar phosphate or tris-maleate buffer. pH 7.4, for 5-15 min at room temperature. To study the effect of increased electrolyte concentration on stain selectivity we added I molar sodium chloride to the tris-maleate buffer in some cases. Consecutive ultrathin sections on grids were stained in the same way and briefly rinsed in distilled water. Other ultrathin sections were stained conventionally with 4 per cent uranyl acetate and lead or examined unstained.

Ruthenium red in phosphate buffer stained mast cell granules intensely, but nuclei and other peritoneal cells remained unstained or showed at the most a faint tinge under both the light and electron microscopes (Figs. 1-3). When tris-maleate buffer was used as solvent for the stain. however, selectivity was not as good (Fig. 4), for nuclei also became electron dense. When the electrolyte concentration was increased to 1 molar by adding sodium chloride to the stain and tris-maleate buffer, staining of nuclei was considerably suppressed, while mast cell granules still reacted quite intensely. If the idea of critical salt concentration" which implies that the capacity of polyammonium salts to precipitate giveosaminoglycans is determined by the electrolyte concentration, is also valid for the interaction of ruthenium red with mast cell granules, the results suggest that the acid glycosaminoglycan demonstrated was heparin. agrees with the results of vital staining with ruthenium red2. Thus, embedding in GMA did not seem to interfere with the binding of ruthenium red to granule heparin.

The marked variation in granule electron density seen after vital staining2 was not apparent after sections had been stained. The variability observed in the former case might thus be caused by variation in the degree of penetration of the stain through the perigranular membranes. This will be further investigated.

When the uranyl acetate and lead were used there was no specific increase in granule electron density

These results demonstrate that the hydrophilic embedding material GMA makes possible the use of a conventional histochemical technique in ultrastructural studies. In addition, it is possible to overcome the penetration problems connected with high-molecular reagents. Staining of consecutive sections also makes it possible to compare the effects of various light and electron microscope techniques on the same specimen.

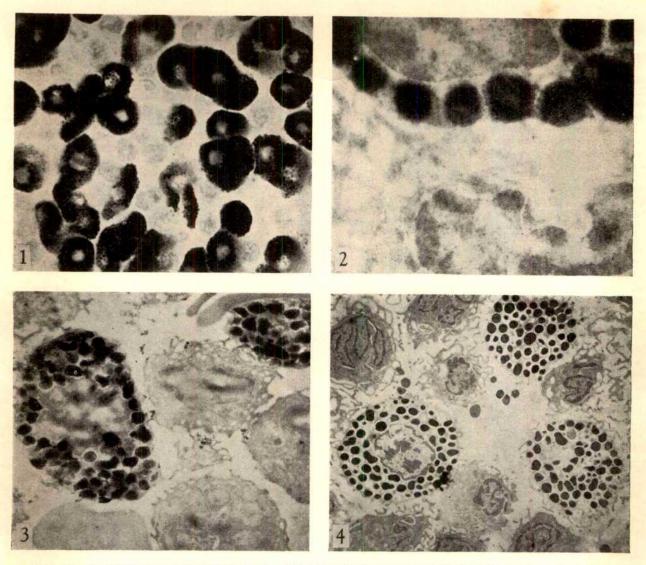

Fig. 1. Rat peritoneal cell suspension fixed in formaldehyde. A GMA section (1 μ thick) was stained with 0.001 molar ruthenium red in phosphate buffer for 5 min. Mast cell granules stained intensely, contrasting with pale nuclei and other cells. (×1,050.)

- Fig. 2. Ultrathin section from same specimen as in Fig. 1, stained in the same way for 15 min. There is a similar contrast between mast cell granules and other cell organelles as in Fig. 1. There is no additional electron staining in this or other figures. (×14,500.)
- Fig. 3. Peritoneal cell suspension fixed in glutaraldehyde. The ultrathin section was stained as in Fig. 2. Mast cell granules are rendered selectively electron dense. (× 6,750.)
- Fig. 4. Cell suspension fixed in glutaraldehyde. This section was stained for 5 min with 0-001 molar ruthenium red in tris-maleate buffer.

 Mast cell granules are markedly electron dense but nuclei have also taken up stain. (×4,750.)

We thank Dr W. Bernhard and his staff at the Institut de Recherches sur le Cancer, Villejuit, France, for showing us their technique of GMA embedding.

PHYSIOLOGY

Cerebral Composition and Function in Experimental Brain Injury in the Rat

NEURONAL activity is dependent on the ability of nervous tissue to control the concentration of electrolytes across the nerve cell membrane. The most important component of this process is the active extrusion of sodium from the neuronal cytoplasm against an osmotic gradient. A nerve impulse is normally initiated by the production of an area of increased permeability on the cell surface which allows the outward flow of potassium ions and the inward flow of sodium ions1. After the passage of the impulse, energy is required to restore the electrolyte distribution associated with the resting polarized state1. Nerve impulses can also be initiated by altering the electrolyte content of the fluid surrounding the neurone. Electrolyte disturbances occur in oedematous brain following trauma and cold injury and have been studied in detail by Pappius and Gulati, but in such conditions the mechanism of water accumulation and other ionic changes are not known². The following experiments were carried out on anoxic-ischaemic brain damage in rats³ in order to investigate the role of changes in the electrolyte and water content of the brain in the production of the hemiplegia and convulsions which occur in this condition, and their relationship to cerebral protein synthesis and energy production.

Brain damage was induced in adult and immature white Wistar rats of either sex by ligation of the right common carotid artery in the neck followed by intermittent exposure of the animal to 1 atm. of nitrogen for 30 min as described by Levine³. This resulted in hemiplegia in approximately 70 per cent of animals. Convulsions occurred in twelve of the thirty-nine hemiplegic adults and in none of the immature

animals. Previous experiments had indicated that only the most severely hemiplegic rats developed convulsions and these had a mortality rate of almost 100 per cent during the 48 h after inducing brain damage. Rats were killed immediately after the anoxic episode and at intervals up to 108 h afterwards. The brains were rapidly removed and the forebrain separated from the hindbrain by sectioning the midbrain. The cerebral hemispheres were separated by a median sagittal cut and weighed separately. The hemispheres were then dried to constant weight at 105° C. The dried brains were dissolved in 0·1 normal nitric acid and the sodium and potassium contents determined by flame photometry and the chloride contents determined by a mercuric nitrate method⁴.

Figure 1 shows the water and chloride content of the anoxic-ischaemic hemisphere at different intervals after induction of the brain injury. During the first half-hour little change from the control values was observed, although some animals did exhibit moderate increases in cerebral water content. Animals which developed convulsions at this time had cerebral water and chloride levels within the normal range. One and a half hours after injury no abnormality was found in the brain chloride of convulsing and non-convulsing animals. The mean water content of the right forebrain in the entire hemiplegic group at this time was, however, 1.3 g/100 g wet weight higher than the mean control value. The corresponding increase in the animals with convulsions in this group was 1.9 g/100 g wet weight. After 1.5 h the

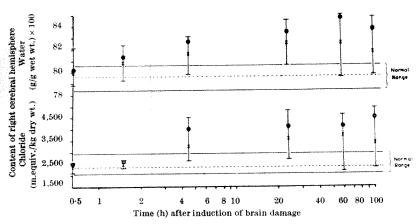

Fig. 1. Water and chloride content of anoxic ischaemic hemisphere at intervals after induction of injury. I, Range of values (between six and ten observations); ×, the mean of this range; and •, the mean value for animals in each group which had fits. The normal range is shown and the interrupted line indicates the mean of the normal.

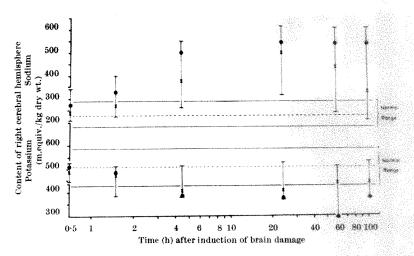

Fig. 2. Sodium and potassium content of anoxic ischaemic hemisphere at intervals after induction of anoxic ischaemic encephalopathy. The notation is the same as in Fig. 1.

mean water and chloride contents of the test hemispheres were consistently higher in convulsing animals than the mean values for the hemiplegic group taken as a whole. The maximum mean water and chloride content of the injured area of the brain was attained at 24 h and 60 h, respectively, after which both of these declined. There was a wide scatter of results, but consistently high values for both water and chloride content occurred between 4.5 and 108 h in the animals which had convulsions (Fig. 1).

The sodium and potassium contents of the hemisphere also showed maximum deviations from the normal at 24 h. From 1·5 h onwards the rats with fits had more marked changes in cerebral sodium and potassium concentrations than the mean values for the group as a whole (Fig. 2). No significant change was seen in sodium and potassium content in the first 0·5 h, but from 1·5 h after brain injury there was a consistent drop in potassium and increase in sodium content of the anoxic ischaemic hemisphere. The values for these electrolytes also showed a mean maximum change at 24 h and a slow return towards the normal range thereafter. After 1·5 h there were bigger changes in animals with convulsions than in the hemiplegic group as a whole.

Out of forty-nine immature rats treated with the Levine procedure, only eight showed water and electrolyte changes in the right cerebral hemisphere. All of the latter animals were more than 7 days old. The abnormalities were quantitatively similar to those occurring in the adult rats.

By comparing the increase in cerebral water content with increases in sodium and chloride in individuals with brain damage, the presumptive sodium and chloride content of the cedema fluid was calculated. There was no significant variation in these values at different intervals after brain damage and with different degrees of severity of oedema or functional disturbances. Table 1 shows that the mean sodium content for the cerebral oedema fluid for all adult hemiplegic animals was 285.0 m.equiv./l. and the mean chloride content was 1,630·0 m.equiv./l. Table 1 also shows that the most severely affected rats (that is, those with convulsions) had sodium and chloride concentrations in their oedema fluid which were similar to those of the group as a whole. There was a significant decrease in the chloride content of the

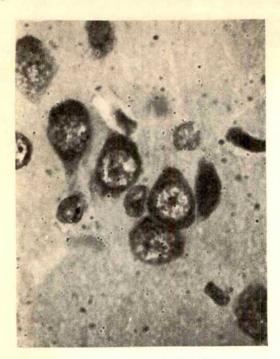

Fig. 3. Autoradiograph of left (control) cerebral cortex of anoxic ischaemic rat tissue during anoxic episode following an injection of tritiated glucose. There is a great reduction in the number of radioactive grains compared with controls (haematoxylin and eosin, ×960).

oedema fluid in immature hemiplegic rats. These values for the calculated sodium and chloride content of the oedema fluid are much greater than the concentration of these electrolytes in the plasma. This indicates that the electrolyte changes in the brain are not merely the consequence of capillary damage with a release of plasma into the tissues. A more likely explanation is that the electrolyte changes are part of a widespread intracellular process and that capillary damage plays only a contributory part. Also, the sodium and chloride concentrations in the plasma of immature rats are higher than those found in adult rats (personal communication from M. J. Seller), whereas their cerebral oedema fluid contains equal or lower concentrations of these ions compared with the adults.

The results suggest that animals with anoxic-ischaemic cerebral damage show evidence of a breakdown of active ionic transport in the brain after the animal has been returned to an atmosphere of air. This disturbance appears to be maximal about 24 h after the end of the anoxic episode and at this time the rats with the more marked functional disturbances showed the greatest oedema and electrolyte changes. Nevertheless, in the early hours after the induction of the brain lesion there was no correlation between functional disturbances and cerebral electrolyte abnormalities-even animals with marked hemiplegia and convulsions showed normal values for cerebral water and electrolytes. Thus other factors must produce this type of cerebral disfunction. Anoxic anoxia alone can lead to fits and yet rats which have convulsions in an atmosphere of nitrogen have no cerebral oedema5. The mechanism of anoxic convulsions is presumably depression of regions

of the brain with the highest oxygen requirement caused by the acute cessation of oxidative phosphorylation in these selectively vulnerable neurones. Fits could result if inhibitor activity were abolished before motor activity. It seems probable that a failure of oxidative phosphorylation can also persist after an episode of anoxia and following return to a normal atmosphere. Suggestive evidence for post-anoxic inhibition of the tricarboxylic acid cycle was provided by measurement of brain lactate and adenosine triphosphate (ATP) at intervals up to 24 h after the production of the Levine type of brain damage*. Normal rat brain contained 4.2 µmoles of lactate/g of fresh brain and the anoxic ischaemic brain contained 8.0 µmoles of lactate/g of fresh brain between 0.5 and 24 h after There was a simultaneous decrease in cerebral ATP. The mean normal value was 2·2 μmoles/g of fresh tissue and the post-anoxic values varied between 0.3-1.4 µmoles/g of fresh tissue. Although there was a decrease in total glucose uptake by post-anoxic brain7 the accumulation of lactate indicated that glycolysis was less severely inhibited than the tricarboxylic acid cycle. Confirmatory evidence for a prolonged block in tissue respiration is the marked decrease in in vitro oxygen uptake by post-anoxic brain8. One mechanism by which the tricarboxylic acid cycle is impaired is loss of succinic, isocitric, lactic and malic dehydrogenases in both neuronal and glial elements of anoxic brain9,10. This does not seem to be caused by an early increase in lysosomal activity, for there is an initial fall in acid phosphatase, but it could be a consequence of a failure of protein and nucleotide synthesis11. In the absence of accelerated enzyme removal, the cessation of protein synthesis precedes enzyme deficiency because of the time taken for normal protein catabolism.

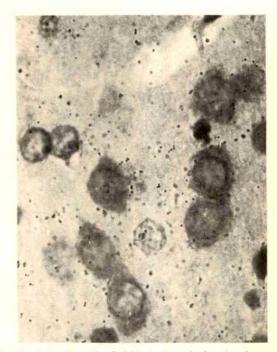

Fig. 4. Autoradiograph of right (test) cerebral cortex from same animal as in Fig. 3; a similar reduction in grain density has occurred compared with the left cortex (haematoxylin and eosin, ×960).

Table 1. CALCULATED SODIUM AND CHLORIDE CONTENTS OF OEDEMA FLUID IN THE ANOXIC-ISCHAEMIC HEMISPHERE OF ADULT AND IMMATURE HEMIPLEGIC RATS

		Sodium			Chloride		
Group	No. of observations	Mean	S.E. of mean	Significance (t test)	Mean	S.E. of mean	Significance (t test)
Adult hemiplegic with	8	296-0	47-4	t = 0.275 P = 0.7 - 0.8	1,557-0	255.5	t = 0.541 P = 0.5-0.6
All adult hemiplegic	20	285.0	24-3	t = 1.315	1,630-0	159.7	t = 2.92

Concentrations are measu	red in m.equiv./l.						

This will vary in different cell types and in different areas of the brain. Nevertheless, de novo protein synthesis is decreased as soon as the animal is placed in an atmosphere of nitrogen. In the present experiments, adult rats (body weight 150-180 g) had their right common carotid arteries ligatured and were injected with 150 µc. of tritiated D-glucose or L-lysine. The rats were then placed in an atmosphere of nitrogen for 10 min. The animals were then killed and autoradiographs were prepared as described before¹². Autoradiographs of both hemispheres (Figs. 3 and 4) showed a decrease in grain numbers compared with normal animals. The grains represent radioactive glucose or amino-acid incorporated into protein. Two hours after the end of the anoxic episode, however, the control (left) hemisphere showed the distribution and number of grains similar to normal controls (Fig. 5), whereas evidence of very little protein synthesis was seen in the anoxic ischaemic hemisphere of the same animal (Fig. 6).

An additional factor which could produce deficiency of respiratory enzymes is early loss of intracellular cerebral dehydrogenases into the plasma after brain damage¹².

Severe endothelial swelling can occur immediately after the induction of the Levine lesion but is not invariably seen under the electron microscope in this condition¹³. Thus tissue oxygenation could be impaired when swelling of capillary endothelial cells was of a sufficient degree to produce occlusion of the vascular lumen.

This evidence suggests that an acute episode of cerebral anoxia—and thus a period when aerobic respiration is inhibited—can lead to more permanent changes in the brain which persist for many hours after the return of the animal to a normal atmosphere. These biochemical lesions could produce a sustained deficiency of aerobic energy production and could therefore be related to the flow of sodium into the brain.

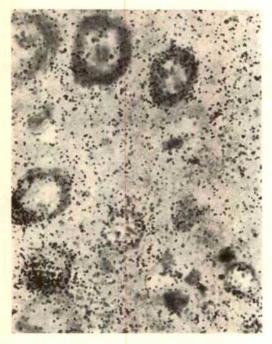

Fig. 5. Autoradiograph of left (control) cerebral cortex of anoxic ischaemic rat 6 h after the anoxic episode and 1 h after injection with tritiated glucose. Normal grain density and distribution (haematoxylin and cosin, × 960).

It seems unlikely that oedema alone can permanently damage the brain. Administration of sufficient water to adult rats to produce cerebral oedema and convulsions does not lead to any histological change 24 h afterwards¹⁴.

Nevertheless, the water content of the brain in rats injected with water and which had convulsions was similar to that found in the right hemisphere of convulsing animals 24 h after applying the Levine procedure¹⁴. Thus fits in rats 1 day after an anoxic episode could be partly caused by their cerebral oedema, but in these animals there is also a deficiency in aerobic metabolic processes which in itself can produce convulsions.

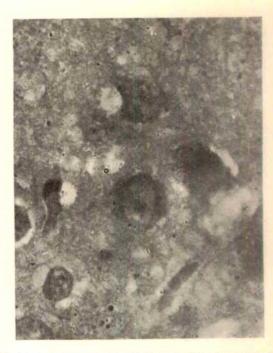

Fig. 6. Autoradiograph of right (test) cerebral cortex from same animal as in Fig. 3. There is a striking reduction in grain counts in the absence of definite histological change (haematoxylin and cosin, ×960).

A characteristic feature of the oedema described in these experiments is the initial delay in its appearance followed by progression in the first 24 h. A relatively small failure of the energy dependent sodium extrusion mechanism could lead to a continuous accumulation of sodium and water within the brain. Although protein synthesis is inhibited as soon as anoxia begins, enzyme loss is delayed for a variable interval after this until the existing enzyme protein is catabolized. Thus the functioning of the tricarboxylic acid cycle would progressively deteriorate after the end of the anoxic episode. could result in an increasing failure of sodium extrusion. The failure of anoxia to produce oedema and electrolyte changes in the brain of rats before the end of the first week of life could be a result of the diminished tendency of the rat brain to develop oedema before the age of 11 days after osmotic disturbances¹⁵. Another important possibility is the resistance of the immature animal to anoxia. This seems to be partly caused by a high glycogen content of the myocardium, the relatively greater utilization of anaerobic glycolytic metabolic pathways and their poikilothermic behaviour when deprived of oxygen¹⁶. It is not until the second week after delivery that a differential concentration of sodium and potassium occurs across the neuronal membrane and this seems to be related to an increased utilization of mitochondrial aerobic respiratory mechanisms17. The lower trans-neuronal differential electrolyte concentration suggests that a breakdown in energy dependent transporting mechanisms would result in a smaller flow of electrolytes. This is a possible explanation of the lower chloride content of the oedema fluid in the immature rats compared with the adults.

Response Characteristics of Neurones in an Insect Brain

Units have been found in the tritocerebrum of the locust which respond in a complex fashion to visual stimulation. These responses differ in several respects from those of units in the protocerebrum, optic lobes and ventral nerve cord1-8.

Adult locusts (Schistocerca gregaria Forskål) from crowded laboratory culture were used. The head was waxed into a rigid frame which did not obscure vision, and the wings and metathoracic legs were removed; the animal was otherwise intact and no anaesthetic was used. A silver wire was implanted dorsally in the abdomen as the indifferent electrode. An aperture was cut in the frons, and the right tritocerebrum was exposed. The median ocellar and both antennal nerves were cut, the latter to abolish antennal muscle contraction. A varnished tungsten microelectrode was inserted into the tritocerebrum immediately beneath the antennal lobe, and recordings were made in the neuropile lying anterior to the descending tracts running to the circumoesophageal connectives. Action potentials were amplified and recorded together with stimulus markers on magnetic tape, and these data were subsequently analysed with a gated amplitudesensitive counting device. All experiments were carried out in photopic conditions with a background luminance of 1.3-2.0 log₁₀ cd/m². Stationary spots of light were projected on to a large screen placed 42 cm from the eye. These spots were between 0.3 and 2.0 log units brighter than the background illumination. Stimulus intensity was controlled by neutral density filters and the diameter of the spots varied in the range of 30' to 25° subtended at the eye. For experiments on moving stimuli a black disk subtending an angle of 4° at the eye was moved manually at approximately 40°/sec, being held at the end of a long glass rod. During a sequence of movements along an axis, successive movements were in opposite directions; for example, forward/back/forward. . . . some instances the disk was attached to a pendulum. In the initial control sequences, an interval of at least 2 min elapsed between successive movements; during an experimental sequence the interval was about 2 sec. We have been able to record the discharge of individual units for more than 24 h and experienced little difficulty in holding units for about 5 h.

The units we have studied responded to movement anywhere in the visual field of the contralateral eye, and this article is based on a detailed analysis of eighteen out of more than fifty such units recorded from twenty All units were tested briefly for multimodal responsiveness using clicks and puffs of air applied to the body surface. None showed a response to these stimuli.

The rate of "spontaneous" discharge of all units was low, varying from 2 to 60 impulses/min, with a mode of about 10/min. Only half the units gave any response to stationary spots of light, and these gave weak "on" and 'off" discharge to most stimuli irrespective of the size and intensity of the spot. This finding suggests that a spot of light elicits both excitatory and inhibitory effects which are interacting and finely balanced. The shortest latency of the "on" response was 40 msec. It is difficult to make meaningful comparisons with latency measurements obtained by other workers, but 40 msec is longer than the latency of a response to a test flash in the optic lobe of Locusta² and is in the extreme upper limit for protocerebral units in Sphinx⁶. Multimodal neurones in the optic lobe of Locusta, however, have visual latencies varying between 30 and 200 msec (ref. 5).

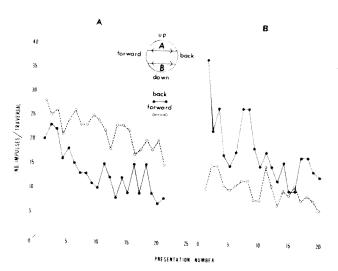

Fig. 1. Response of a unit to movement of a black disk in the visual field, which here and in Fig. 2 is represented by the inset circle. A line within the circle shows the line of traversal of the disk, the direction of movement being indicated by the arrows. The forward/back line is horizontal and parallel to the long axis of the insect's body. The responses to movement (of approximately 60° at the eye) along the line indicated by A in the inset are plotted in graph A. The disk was moved forward and backward repeatedly. The number of spikes elicited by each successive movement is plotted, a separate curve being constructed for each direction. Forward movements along line A constantly evoked a larger response than backward movements. When the disk was moved along line B parallel to but displaced 12° downward from line A, the preferred direction was backward (graph B). Directional effects were thus not homogeneous throughout the field. Although the responses waned, the directional effects were maintained throughout a sequence of presentations.

All units gave a high frequency burst to movement and most responded more vigorously when the disk was moved in one direction across the visual field than when it was moved in the reverse direction. None of the units was inhibited by movement, in contrast to those described by Horridge et al.5 and Collett and Blest?. When the movements were repeated the response rapidly waned, although the directional effect was sometimes maintained. the unit the responses of which are plotted in Fig. 1A fired more vigorously when the disk was moved forward along a horizontal line than when it was moved backward along the same line. A difference in response was maintained through many successive forward/backward presentations during which the magnitude of both responses declined.

The directional effect was usually maintained for movements along parallel lines, but exceptions were not rare.

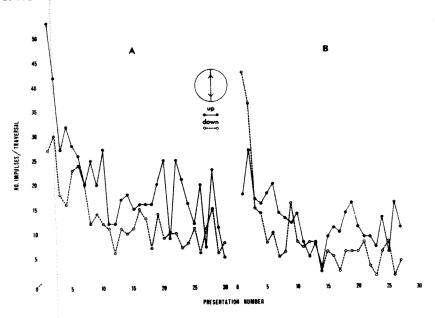

Fig. 2. An example of primacy reversal. A, When the disk was moved first upward and then downward, the to and fro movement being repeated thirty times, there was a clear preference for up. At the end of the sequence the stimulus was withdrawn for 5 min and a second sequence (B) then commenced, the initial movement being down. This was now the preferred direction for the first two pairs of movements, after which the up preference was re-established.

For example, after the sequence of movements which evoked the discharge plotted in Fig. 1A, the disk was displaced 12° downward and moved forward and backward along a line parallel to the first. The directional effect was reversed and maintained although the responses

gradually waned (Fig. 1B).

The initial "directional" effect was frequently found to be determined by the order of stimulus presentation, that is, it was not a directional effect but a primacy effect. When a sequence of to and fro movements along a given line was performed, a directional effect was frequently observed at least for the first two or three movements at When the sequence was the start of the sequence. repeated after a pause of a few minutes, but with the first movement in the opposite sense to the first movement of the original series, the directional effect was frequently reversed. In twelve units which were tested in both the up/down and back/forward directions, twenty of the twenty-four cases showed primacy reversal of this sort. The effect seems to be similar to that exhibited by a fibre in the optic nerve of crayfish. An example is given in Fig. 2. In this experiment, two sequences of movements along a vertical line were made. In one sequence the first movement was upward (Fig. 2A); there was a clear directional effect, upward being the preferred direc-When, however, the initial movement was downward (Fig. 2B), this was the preferred direction for the first two pairs of movements. As the response declined the original preference was restored. Thus the magnitude of the initial response is largely determined by the order of presentation of stimuli (for example, upward first or downward first) rather than by an inherent directional selectivity. It thus seems unwise to classify a unit as directionally selective in the absence of any test for primacy reversal.

Once the response to a given movement had waned a discharge could usually be evoked by moving the disk in some other part of the visual field or by withdrawing the stimulus for some time before moving it again along the original axis. In the latter case, a rest of several minutes was usually sufficient to restore the response, though

occasionally this was not achieved even after a pause of several hours. It is unlikely that this prolonged effect was caused by a deterioration of the preparation because a vigorous response could be elicited by movement in some other part of the field.

Others^{5,7} have shown that some units in the optic lobes are excited by movement in one direction, and are inhibited by movement in the opposite direction. Primacy effects would ensue if complementary cells, with properties similar to those described by these authors. possessed mutually inhibitory connexions—the first cell stimulated by movement in its preferred direction depressing the subsequent response of the other to movement in the reverse direction. The units described in this communication may be synaptically connected to arrays of such complementary cells. Alternatively, both primacy and "directional" effects could be produced by a complex response decrement in a non-directionally selective system of neurones.

Pattern of Cortical and Thalamic Connexions of the Somatic Sensory Cortex

The constituent cells of any architectonic subdivision in the somatic sensory and visual regions of the cerebral cortex respond to peripheral stimuli of a different nature from those which excite cells in other subdivisions. These individual differences have been thought to be principally dependent on afferent thalamic connexions or on cortical association connexions with other subareas1,2, but other factors may also be important, particularly because the various subareas also differ in their callosal connexions3,4, and because cortico-fugal influences may modify the activity of thalamic neurones. As a consequence, in any interpretation of these functional differences it is advisable to take all the extrinsic connexions into account. The patterns of thalamic and cortical connexions of the somatic sensory cortex have been examined in the cat and monkey using experimental neurohistological techniques. distribution of degenerating fibres, following lesions in the thalamus and in the somatic sensory and other cortical areas, has been studied by the Nauta method6 and with the electron microscope.

In the cat, large lesions which destroy the first and second somatic sensory areas of one hemisphere cause degeneration in several parts of the forebrain. In the ipsilateral cortex these are: the motor cortex (area 4); a portion of area 6; and one of the parietal fields, area 5. In the contralateral cortex, only the first and second somatic sensory areas show degeneration and this is restricted to those regions in which the face, trunk, tail and proximal parts of the fore and hind limbs are represented7,8. In both the first and second areas, regions related to the more distal segments of the limbs do not receive commissural afferents from any part of the opposite cerebral cortex. Neither of these latter regions lies within the confines of a single cytoarchitectural field10. In the thalamus, degeneration is found in the nucleus ventralis posterior and the medial division of the posterior

nuclear group 11,12.

The organization of these connexions was examined by placing small lesions in different parts of the first and second somatic sensory areas and in other cortical regions. With regard to the commissural connexions of the first somatic area, it was found that regions in this area which are related to the distal parts of the limbs neither send nor receive commissural fibres. With this exception, the callosal connexions of the first area are organized so that any part projects to a symmetrical point, only, in the contralateral first area, and to a region in the opposite second area which is related to the same part of the periphery. In the second somatic sensory area also, the region related to the distal segments of the limbs does not send or receive commissural fibres; those regions which are related to the trunk, tail and proximal segments of the limbs give off commissural fibres, but these terminate entirely in symmetrical regions of the opposite second area. Regions related to the face, however, project both to symmetrical regions of the contralateral second area and to a small portion of the opposite first area containing the bilateral representation of the face^{7,8}. Electron microscopy has shown that degenerating commissural axons in both the first and second somatic areas terminate on spines attached to dendrites of small and medium size in all cortical layers but especially in the deeper parts of layers I and III and in layer IV.

The association connexions of the somatic sensory areas can be considered as both intrinsic and extrinsic. Lesions in one of the larger functional subdivisions of the first area cause degeneration throughout the same subdivision but not in other subdivisions, while damage to any part of the second area results in degeneration throughout the whole second area. The functional sub-

divisions of the two areas are reciprocally connected and electron microscopy shows that the fibres joining them terminate on dendritic spines chiefly in layers IV to VI with an occasional terminal in the more superficial layers, especially layer I. The subdivisions of the first and second areas are also reciprocally connected with their counterparts in the motor cortex and each has a small projection to a part of area 6 in the region of the supplementary motor areas. Only the first somatic area projects to area 5 and this projection is organized so that hindlimb, trunk and tail regions project to those parts of area 5 situated in the splenial and lateral gyri, while face and forelimb regions project to those parts in the anterior and middle suprasylvian gyri; the latter region has been described as a third somatic sensory projection area13. With the exception of the motor cortex, no other cortical area sends fibres to the somatic sensory regions.

Both components of the postero-ventral nucleus project in a topographically organized manner on the first and second somatic sensory areas14, and all three of the cytoarchitectural divisions of the first area receive the terminations of thalamo-cortical fibres. Electron microscopic studies of the first area following thalamic lesions indicate that most of these fibres terminate on spines or shafts of dendrites of medium size in layer IV and in adjacent parts of layers III and V. A few degenerating terminals also appear on dendritic spines in the more superficial parts of layer III and in layer I. Cortico-fugal fibres in turn project from both the first and second somatic areas back to the nucleus ventralis posterior and also to the medial division of the posterior thalamic nuclear group. The projection to the former is organized so that only parts of the cortex receiving fibres from a specific portion of the nucleus send fibres back to it. Following lesions in either the first or the second somatic sensory areas, degenerating terminals have been seen with the electron microscope ending axo-axonically and axo-dendritically in the nucleus ventralis posterior.

In the monkey, in which the association and callosal connexions of the first somatic sensory area are arranged in a similar manner to those of the cat, it has been possible to restrict lesions to single cytoarchitectural fields. Ipsilaterally, the parts of these fields situated within one of the functional subdivisions of the first area are reciprocally connected with one another and with parts of the second somatic and motor areas which are related to the same portion of the periphery. Each field has, in addition, an organized projection to area 5 and sends a small number of fibres to the supplementary motor area. The regions functionally related to the distal segments of the limbs⁸ include portions of areas 3, 1 and 2 and do not send or receive commissural fibres; other parts of the three fields project to both the first and second somatic areas of the opposite hemisphere, but the projection to the first area is restricted to a symmetrical region in the

homotypical field only.

The observations recorded here demonstrate that in each hemisphere portions of the first and second somaticsensory areas in which a given part of the periphery is represented are reciprocally connected with one another, with a similarly related part of the motor cortex, and in an organized manner with the postero-ventral nucleus of the thalamus. In contrast, the callosal connexions of the two areas display a certain lack of uniformity: the first somatic area sends fibres to both the contralateral first and second areas; the second area sends most of its fibres to the opposite second area only; the distal limb regions of each area lack interhemispheric connexions entirely. This pattern of connexions bears many similarities to that which has already been demonstrated in the visual cortical areas of the cat. In both cases, the relevant thalamic nucleus projects to all the known functional and architectural subdivisions of the respective areas 15,16. In the somatic sensory cortex all these subdivisions are interconnected by cortical association fibres and the same seems

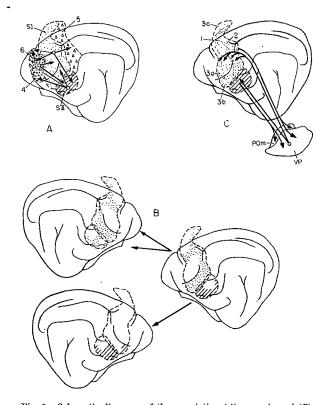

Fig. 1. Schematic diagrams of the association (A), commissural (B), and thalamic (C) connexions of the somatic sensory areas in the cat. Somatic areas are drawn after Woolsey', and in A and C cytoarchitectural details have been added following Hassler and Muha-Clement's whose numbering scheme is retained (SI, first somatic sensory area; SI, second s group).

to be true for the subdivisions of the visual cortex which have been studied^{2,17}. In addition, both cortical areas are connected to the same restricted portion of area 6 (ref. 17). The callosal connexions of both areas do not terminate throughout the corresponding region of the contralateral hemisphere^{9,17}. In the somatic sensory areas, those parts which are commissurally interconnected are the regions related to part of the body close to the midline, and there is evidence that the restricted parts of the visual cortex which are commissurally connected are "best excited by visual stimuli near the midline"18. Finally, there is good evidence from this and other studies that the somatic and visual areas are reciprocally connected with their respective thalamic relay nuclei and also send fibres to one other part of the thalamus—the posterior group in the case of the somatic areas and the nucleus lateralis posterior in the case of the visual areas^{17,19}. It would be interesting to know whether the cortical connexions of other sensory systems are also similar and, if so, whether there is, perhaps, some basic pattern common to all.

Comparison of the Rate of Habituation of the Flexor Reflex between Both Hind Limbs tested sequentially in the Rat

WE have developed a technique for measuring the electromyographic discharge and isometric tension in the biceps femoris muscle of the conscious rat1, which has enabled measurements of latent period, duration of electromyographic discharge and tension to be made during habituation of the flexor reflex in response to repeated uniform stimuli applied to the web space of the ipsilateral hind limb. Establishment of habituation of the reflex has been assessed from: (a) the number of stimuli required before the animal ceased to respond to the standard stimulus; (b) the progressive increase in latency of the reflex response; (c) the progressive reduction in total duration of electromyographic discharge; and (d) the decrease in tension developed. Habituation of the flexor reflex has been demonstrated with this technique in both intact rats and rats tested 4 days after spinal transection.

We have now compared the rate of habituation of the flexor reflex recorded separately from each hind limb of the same rat. Assessment of habituation was made using all four criteria, but for simplicity of quantitative presentation, values for criterion (a) only are given here, although the significance of assessment by criteria (b), (c) and (d) is referred to.

In three intact rats the right limb was tested first, and in a further three rats the left limb was tested first; in each case the other limb was tested 1-2 days later. There was no significant difference in the rate of habituation calculated from changes in latency, tension developed and duration of electromyographic discharge when a comparison was made between the right and left limbs; nor was there any significant difference in the mean number of stimuli required to achieve complete loss of reflex response. When a comparison was made between the first and second limbs tested, the rate of increase in latency and decrease in tension developed and decrease of duration of electromyographic discharge was significantly lower in the second than in the first. The second limb tested required significantly more stimuli than the first to achieve complete loss of the flexor reflex response (see Table 1).

A similar experiment was performed on six rats which had undergone spinal transection at the level of T.10

Table 1.

			quired to achieve		
	No. of	complete loss of	reflex response		
	observa-				
	tions	Right leg	Left leg	t	\boldsymbol{P}
Intact rats	в	251 ± 51	255 ± 47	0.06	> 0.9
Spinal rats	6	154 ± 34	187 ± 35	0.70	> 0.5
		First leg tested	Second leg tested		
Intact rats	6	176 ± 12	327 ± 50	2.90	< 0.05
Spinal rats	6	170 ± 24	171 ± 38	0.02	> 0.0

4 days previously. There was no significant difference in the rate of habituation calculated from changes in latency, tension developed and duration of electromyographic discharge when a comparison was made between the right and left hind limbs, nor was there any significant difference in the mean number of stimuli required to achieve complete loss of reflex response. There was no significant difference in the number of stimuli required before the animal ceased to respond, nor was there any significant difference in the rate of change of latency, tension developed and duration of electromyographic discharge when comparison was made between the first and second limbs tested (see Table 1).

When the number of stimuli required to achieve habituation in the second limb was expressed as a percentage of that required by the first limb, the mean value obtained for the intact rats was 187 ± 27.0 per cent, and for the spinal rats 101.8 ± 10.9 per cent; these percentages differed significantly (P < 0.001).

In intact rats habituation of the flexor reflex to repeated application of the uniform stimulus occurred at a lower rate in the second limb tested than in the first, which indicated that previous "experience" of the stimulus was important in the establishment of habituation. In spinal rats the rate of habituation of the flexor response was the same in both hind limbs, which suggests that utilization of previous "experience" of the uniform stimulus involves, at least in part, supra-spinal centres. These observations indicate that there is a supra-spinal mechanism which delays the establishment of habituation in the intact rat. This mechanism would therefore have an opposite action to the frontal areas of the cortex, because in the intact animal the frontal areas of the cortex must act to facilitate the establishment of habituation, because frontal lesions impair the process of habituation (refs. 2 and 3 and our unpublished work).

Irreversible Inhibition of Acetylcholinesterase by Dibenamine

WE are investigating the idea1 that the muscarinic receptor and the anionic site of acetylcholinesterase (AChE) are identical by comparing the kinetics of inhibition of AChE and the receptor by certain irreversible inhibitors.

Belleau and Tani2 have recently shown in a qualitative manner that N,N-dimethyl-2-chloro-2-phenethylamine (C₆H₅.CHCl.CH₂.NMe₂), which spontaneously produces the ethyleniminium ion in aqueous solution, is an irreversible inhibitor of AChE at the anionic compartment. We have found that a related compound, dibenamine $((C_6H_5.CH_2)_2N.CH_2.CH_2Cl)$, slowly inhibits the enzyme through its ethyleniminium ion, the reaction in acid solution involving a group on the enzyme with approximate pK_a 5.8, whereas in alkaline solution a fast reaction occurs with a group on the enzyme with approximate pK_a 9.2.

The reaction between dibenamine $(0.24-0.95 \times 10^{-4})$ molar) and bovine AChE at 25° C in 0.2 molar sodium chloride and gelatine media at pH 9.5 was followed by withdrawing samples at predetermined intervals and assaying the enzyme activity by the pH-stat method using 0.002 molar acetylcholine bromide as substrate. A linear plot of $\log (a-x)$ versus t for the reaction, where (a-x) represents the enzyme activity remaining at time t,

for different concentrations of enzyme with a fixed inhibitor concentration showed that the reaction followed first order kinetics of the form, $v = k(Db)(AChE) = k_{obs}$ (AChE). The second order rate constant, k, however, progressively decreased with increasing dibenamine concentration, which suggested that an inhibitor-AChE complex was formed before "intramolecular" alkylation of the enzyme in accord with equation (1). Green and Smith4 noted a similar relationship for the reactivation by oximes of AChE inhibited by organophosphorus com-

Inhibitor + AChE
$$\stackrel{K}{\rightleftharpoons}$$
 AChE Inhibitor complex
$$\stackrel{k_5}{\longrightarrow}$$
 Inhibited enzyme (1)

A plot of 1/k versus [dibenamine] gave a straight line with slope $1/k_3$ and intercept K/k_3 which gave approximate values for K and k_3 of 1.56×10^{-5} mol. $1.^{-1}$ and $4.52\times$ 10-2 min-1.

The second order-rate constant k for the reaction between fixed concentrations of inhibitor and enzyme was influenced by the reaction media at low ionic strength at pH 6.5 but only to a slight extent at pH 9.5 (Table 1). These observations may be interpreted in terms of interaction between ions of opposite charge during the reaction at pH 6.5, which would implicate dibenamine in the reaction as its ethyleniminium ion (Db), and, errone-

ously, as shown here, a reaction between the uncharged dibenamine base and the enzyme at pH 9.5.

The reaction between enzyme and dibenamine (19 ml., 0.75×10^{-4} molar) at pH 10.0 was prevented by allowing the dibenamine solution to stand in contact with thiosulphate ion (0.2 molar) for 10 min before addition of the enzyme. In another experiment, the enzyme was omitted and the unreacted dibenamine base extracted with ether. The residue recovered from the ether was dissolved in dilute acid (19 ml.) and this solution was used to inhibit the enzyme in the usual way. The rate of inhibition was comparable with that observed in a control extraction experiment where sodium chloride (0.2 molar) replaced the thiosulphate ion. These experiments firmly establish that the active alkylating species present in dibenamine solution at alkaline pH which is destroyed by the thiosulphate ion is the ethyleniminium ion and not the free base with which thiosulphate is also known to react?.

Table 1. EFFECT OF IONIC STRENGTH ON THE INHIBITION RATE CONSTANT, & 1.mol.-1min-1+

			Tonic str	ength* (I)

* Sodium chloride.
† Dibenamine concentration, 0.71 × 10⁻⁴ molar.

Certain \(\beta \)-halogenoethylamines related to dibenamine are known to alkylate the adrenergic receptor6 and acetylcholinesterase² as their readily formed ethyleniminium ions, but dibenamine gives a very low yield of its ion in aqueous organic solvents7,8 and has not previously been directly observed as an alkylating agent in a biological system. The following scheme (equation (2)) is proposed to explain the observed first order kinetics, where Db is the reacting species, which is based on the premise that the concentration of Db remains constant within narrow limits during the reaction.

Applying the general case of two consecutive first order reactions, then with a reactive intermediate, that is, k_2 (H₂O) $\gg k_1$, its concentration will be very low and may be considered essentially constant because of the existence of a steady state. This view is supported by studies on certain other β -halogenoethylamines which cyclize slowly and give low constant concentrations of ethyleniminium ions for long periods8,10

The rate-pH profile for the reaction using fixed concentrations of enzyme and inhibitor was a sigmoid-shaped curve with a pronounced hump at the foot. A plot of $1/k_{\rm obs}$ against [H+] in the usual way gave the pK_a s of the two groups on the enzyme involved in the reactions which

were approximately 5.8 and 9.2.

The rate-pH profiles obtained for the hydrolysis of substrates by AChE together with other work show that two basic groups¹¹ with pK_a 6.3 (imidazole) and 5.5 and and acidic group¹² with pK_a 9.35 (phenolic hydroxyl of tyrosine) are involved in the catalytic process. The pHrate data in the acidic region can be interpreted either as alkylation of imidazole or as prevention by a protonated imidazole group to binding of the ethyleniminium cation at the anionic compartment of the active site—a situation analogous to that noted for charged competitive inhibitors11. Reaction between the bound ion and an unionized group elsewhere at the active site could then occur.

Effect of Gastric Juice and pH on Inorganic Iron in Solution

THE absorption of ionized iron in humans is influenced by gastric acidity¹⁻³. Ferric ions in solution usually form complex mixtures in which the metal is co-ordinated to a number of hydroxyl ions and in some conditions there is a high degree of polymerization4. Ferrous ions do not undergo such marked changes but tend to be oxidized to ferric forms when the pH approaches neutrality4. Filtration on 'Sephadex' gel has been used in this laboratory to examine the behaviour of iron salts at different pHs and after mixing with gastric juice.

Freshly prepared aqueous solutions of 59Fe-ferric citrate with iron concentrations of 2 µg and 200 µg/ml. and unlabelled ferrous sulphate solution with an iron concentration of 200 $\mu g/ml$. were examined. The solutions of ferric iron were also examined after mixing with an equal volume of freshly aspirated gastric juice which had been neutralized to pH 7 with 0.1 normal sodium hydroxide. Samples (I ml.) were eluted from a column of 'Sephadex G-25', 15 mm in diameter after equilibration with 0·1 molar buffers at pH 2-6·8 and also with 0·1 normal hydrochloric acid. Fractions (2 ml.) were collected. The activity of iron-59 in the fractions was

measured by scintillation counting in a well crystal and the chemical iron content was determined using tripyridyltriazine5.

At pH 1.3 ferric iron behaves as a relatively unpolymerized ionic species. Its peak concentration appears in a corresponding low molecular weight fraction after gel When pH increases above 3.5 ferric iron filtration. appears in fractions which gradually approach the void volume of the column (Fig. 1), in this case corresponding to a molecular weight of about 5,000. This behaviour results from the increasing condensation of ferric ions at increasing pH to form complex ions of high molecular weight. The behaviour of ferrous iron differs in that no change in molecular size seems to occur between pH 1.3 and 6.8. Ferrous iron appears in the fractions in which the smallest ferric ions are found. It shows the same behaviour at concentrations of 2 µg and 200 µg/ml., and the positions of radioactive peaks correspond to those of peak concentrations of chemically determined iron.

When ferric iron mixed with gastric juice is passed through the column at $p{\rm H}$ 6.8 some of the iron appears in the void volume, which indicates that it is bound to a high molecular weight component of the gastric juice (Fig. 2). This portion is smaller and often less discrete at pH 5.5 and is absent at pH 4.3 or lower. The proportion

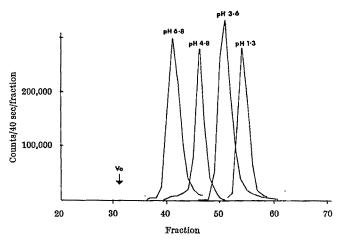

Fig. 1. Radioactivity of fractions obtained after gel filtration of $^{59}{\rm Fe-ferric}$ citrate at different $p{\rm Hs.}$

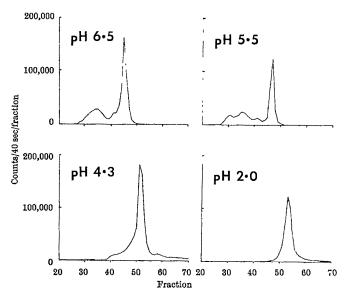

Fig. 2. Radioactivity of fractions obtained after gel filtration of a mixture of ao Fe-ferric citrate and fresh gastric julce at different $p{\rm Hs.}$

of iron in the "bound" peak is approximately the same at both iron concentrations. When gastric juice was first incubated at 37° C for 1 h before neutralization there was little binding of iron.

At a neutral pH ferric ions seem to be larger than ferrous ions. This may be a factor in determining availability of iron for absorption in the small intestine, and it may partly explain the effect of gastric acid on iron absorption and the greater absorption of ferrous iron. Gastric juice does not seem to bind iron in an acid medium and the physiological significance of this phenomenon is uncertain. While no direct inference can be made from these observations regarding the state of iron in the jejunum in vivo, its behaviour in relation to the pH usually found in the upper gastrointestinal tract and its reaction with gastric juice are relevant to the study of this problem. After a meal gastric contents at about pH 2 leave the stomach and traverse the duodenum as a Alkaline secretions in the duodenum do not increase the pH of this bolus to more than 3-4. At the upper end of the jejunum the bolus is mixed with intestinal secretions and acidity fluctuates between pH 4 and 7 (ref. 6). If the behaviour of iron in vivo is similar to that demonstrated in vitro, then intraluminal pH may determine both its availability and the site of absorption.

I thank Tenovus for a grant supporting this work.

RADIOBIOLOGY

Dinitrophenol decreases the Radiation Sensitivity of L Cells

BECAUSE the repair of radiation injury would seem to consume energy, chiefly in the form of ATP, we have studied the response to radiation of L cells, severely depleted of intracellular ATP. We have found that 2,4-dinitrophenol (DNP) can reduce intracellular ATP by about 90 per cent, that L cells treated with DNP for up to 8 h lose none of their reproductive integrity and that treated cells are less sensitive to radiation, particularly at a high dose.

L-929 cells were used as monolayers on Eagle's medium (MEM) supplemented with calf serum (10 per cent serum for monolayers, 17 per cent serum for cell survival studies) in glass bottles. For cell survival experiments, monolayers were trypsinized, counted with a haemacytometer, diluted with fresh medium, and incubated for 24 h at 37° C in an atmosphere of 5 per cent carbon dioxide–95 per cent air. After this attachment period the medium was removed from some of the plates and replaced with glucose-free Hanks solution containing 5×10^{-5} molar DNP, pH adjusted to $6\cdot8-7\cdot0$ with $7\cdot5$ per cent sodium bicarbonate.

After 30 min of contact with DNP, the cells were irradiated with spaced doses of X-rays (150 kVp, 15 m.amp, 6 mm Al HVL, dose rate 100 rads/min; irradiations were performed in conditions of full backscatter). The DNP remained in contact for 2 h after irradiation and was replaced with fresh medium. Control plates, set

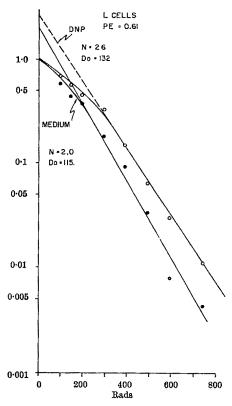

Fig. 1. Post-irradiation survival curve for control and DNP treated cells.

up from the same inoculum, were irradiated at the same time as the plates treated with DNP. After 12 days incubation, the colonies were fixed, stained and counted. Plating efficiencies ranged from 0.42 to 0.65.

Figure 1 shows that treatment with DNP increases both n and D_0 compared with control cells irradiated in medium and the effect is to prolong the shoulder segment. There was some increased survival after the lower doses of X-rays, but the effect is more pronounced with larger doses. For this experiment, the average cellular multiplicity was 1·1 for both treated and control cells.

Table 1 shows the result of a toxicity study with DNP. For this experiment, DNP was left in contact with the cells for various times. Up to 8 h of contact there was no evidence of toxicity; after 8 h there was slightly more survival than in cells maintained in medium.

Table 1. TIME-TOXICITY RESULTS FOR L OELLS

Treat- ment	Time of contact	Plates	Cells plated	Colonies	Average
Control (medium) DNP DNP DNP	2 h 4 h 6 h	3 3 3	60 60 60	32, 36, 34 35, 40, 43 38, 40, 43 42, 39, 40	34±2* 39±4 40±3 40±2
DNP	8 h	3	60	44, 46, 40	43 ± 3

The average cellular multiplicity was 1.04 to 1.1 for both controls and DNP treated cells.

* Standard deviation.

Fig. 2 shows that DNP reduced the intracellular concentrations of ATP. For this experiment, cells were gently scraped from the monolayers with a rubber policeman and suspended in fresh medium at a concentration of about 1.5×10^6 ml. The suspension was stirred gently, aerated and maintained at 37° C. At various times after collection, 1 ml. samples were taken from the suspension, extracted with perchloric acid (PCA)—final concentration 0.5 N—neutralized with potassium hydroxide, and the concentration of ATP was measured by the firefly luciferase method using a liquid scintillation counter¹. When several samples had been collected, the suspension was centrifuged and the medium was replaced by DNP. Additional samples

were taken, the suspension was again centrifuged, and DNP was replaced by fresh medium. As Fig. 2 shows, although DNP produces a rapid decrease in the concentration of ATP, there is a rapid increase after removal of

DNP acts on ATP by uncoupling mitochondrial oxidative phosphorylation. As our results show, DNP is not only non-toxic (at least a 5×10^{-6} M, pH 7, and up to 8 h contact), it promotes increased survival after irradiation. Consequently, short periods of ATP deficiency are compatible with viability, normal colony growth and increased resistance to the effects of ionizing radiation.

Perhaps part of the explanation of our results is in the recent work of Elkind et al.2, who propose that repair of radiation injury in cultured mammalian cells, measured by the paired dose method, may not be a biochemical process in the usual sense. This idea stems from their previous work, which showed that "repair" occurred at low temperatures and in anoxic conditions3. They consider their current data compatible with the concept that repair may be a consequence of a passive (possibly physico-chemical) rather than an active enzyme process.

We consider our results entirely compatible with the data of Elkind et al. We found that immediately after treatment with DNP, synthesis of DNA, RNA and protein in the cells virtually stops4. Consequently, the increased survival after irradiation is paralleled by (and is possibly a result of) a depression of macromolecular synthesis. This agrees with the idea that the repair process is enhanced when cells are treated with cycloheximide,

which inhibits protein synthesis.

Probably the most biologically significant effect of radiation is to produce physico-chemical alterations of the DNA bond structure. As a result, endonucleases and exonucleases would attack the altered site (the "cut" partner of the "cut"—and "patch" group of enzymes) and produce breaks in the DNA molecule. If the breaks were single stranded, then repair could progress by a re-synthesis of the absent segment, using the unbroken DNA strand as a template. If both strands be broken, however, the lesion is probably irreparable7.

The active factor seems to be the nucleases rather than the radiation. Perhaps if the "cut" system of enzymes is held back for a period of time after irradiation—by such agents as cycloheximide or DNP-some relaxation of the physico-chemical distortion of the DNA bonds can occur. After removal of the inhibitor, then, the number of sites requiring "cutting" would be decreased. If, on probability

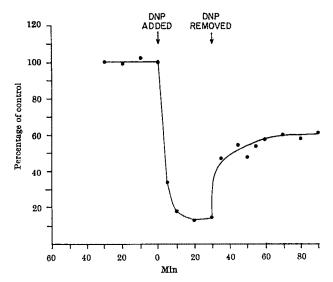

Fig. 2. The effect of DNP on concentrations of ATP in L cells. The results, originally in units of p moles/10 $^{\circ}$ cells, are given as percentage of control.

grounds, some of the potentially double stranded breaks were converted into single stranded breaks, greater postirradiation survival would result.

PATHOLOGY

Acquired Radioresistance of Tumour Cells

RADIORESISTANCE of tumours, which appears as a result of repeated irradiation, was described in 1904 by Lassueur. Certain characteristics were later examined: tumour ploidy²⁻⁶; the state of the mitochondria⁷ and ribosome⁸; the content of sulphydryl groups ,10; the capacity for anaerobic glycolysis11; catalase activity12; and changes in the immune relationships between tumour and organism13. The mechanism of the enhancement of tumour radioresistance, however, remains unknown. In experiments with Ehrlich ascites tumours in mice we have obtained radioresistant strains. This was achieved by intraperitoneal reinoculation preceded by irradiation of the tumour with 300 r. in vivo for 3 consecutive days and a single dose of 1,000 r. in vitro. We made between 50 and 120 passages in these conditions of repeated irradiation. The difference in radiation response of rhythmically irradiated and initial strains of Ehrlich tumour was determined after check-up irradiation with 1,000-3,000 r.

When the inoculation material was irradiated with doses of 1,000 and 2,000 r. and then introduced intraperitoneally the control tumour grew much less than the tumour which had been irradiated repeatedly. In particular, inoculating 106 cells did not result in any development of the control tumour, while the chronically irradiated one showed a marked growth (Fig. 1).

Similarly, when doses of irradiation vary from 1,000 to 3,000 r. and the number of inoculated cells remains constant, the number of animals in which tumours develop is greater when the repeatedly irradiated cells are inoculated (Fig. 2).

The DNA content of repeatedly irradiated strains of an Ehrlich tumour in the fortieth and seventy-first generations was less than that of the initial tumour for 72 h after the check-up irradiation with 1,500 r. Apparently the marked polyploidy of the control tumour is the result of an accumulation of cells with premitotic contents of DNA. To a certain extent this is confirmed by the sudden decrease in the mitotic index, which was between two and ten times lower than that of the repeatedly irradiated strain. The decrease in the mitotic index in the control tumour after irradiation with 1,500 r. may also account for the smaller number of tumour cells in the peritoneal liquid compared with those in the repeatedly irradiated tumour (Figs. 3 and 4). All this implies an increase in the

radioresistance of repeatedly irradiated tumours. Radioresistance was recorded fifteen to twenty passages earlier in vitro than in vivo.

In considering the factors connected with the creation of increased radioresistance we wish to emphasize some of

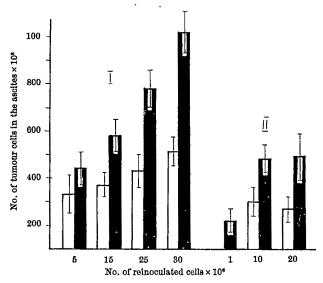

Fig. 1. Growth of control () and chronically irradiated () tumours: taken on the tenth day 1,000 r. (I) and 2,000 r. (II).

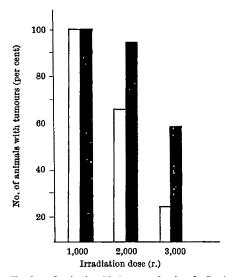

Fig. 2. Number of animals with tumours developed after inoculated 20×10^4 cells irradiated at different doses. \Box , Control; \blacksquare , repeatedly irradiated.

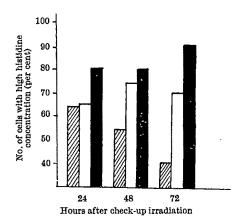

Fig. 5. Number of cells (per cent) with high histidine concentration during three days after check-up, irradiation with 1,000 r. Hatched columns, control; white columns, fortieth generation; black columns, seventy-first generation.

our results. Cytochemical investigation of histidine revealed two types of cells in Ehrlich tumours: the first were strongly stained and the others were only slightly stained. These two types are referred to as cells with "high" and "low" histidine concentrations. After irradiation with 1,500 r., cells with a high histidine content accumulated in the radioresistant strain while the initial control tumour showed fewer such cells (Fig. 5).

Thus the relationship between the increases in histidine content and radioresistance becomes more evident.

We found that the content of sulphydryl groups in soluble proteins of radioresistant strains is 42 per cent greater than in cells of the control strain (Fig. 6). (Sulphydryl groups were estimated by amperometric titration.)

Caspersson and Révész⁹ similarly found an increased content of sulphydryl groups bound to protein (PSH) in cells of radioresistant tetraploid strains of Ehrlich ascites tumours, which were obtained by means of selection. They also found a correlation between the contents of DNA and PSH. We observed an increase of the PSH groups in a

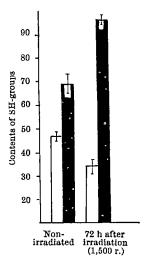

Fig. 6. Content of protein sulphydryl groups in control and chronically irradiated tumours after check-up, irradiation 1,500 r. ☐, Control; ☐, 106th generation.

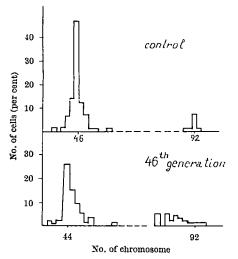

Fig. 7. Chromosomal distribution in chronically irradiated tumour cells.

radioresistant tumour obtained by repeated irradiation; its ploidy was unchanged.

We have also examined by electrophoresis the fractions of soluble proteins in tumour cells. The content of A-globulins was greater in the radioresistant strain than in its initial (control) strain. The content of the A fraction was twice as great in the radioresistant as in the control strain. The content of B-globulins was unaffected. On the third day after irradiation with 1,500 r. the fraction of A-globulins in the radioresistant strain decreased while it increased in the control strain. The content of B-globulins had markedly increased in the radioresistant strain.

The accumulation of B-globulins in the control strain after irradiation seems to be related to an increase in the total protein content of the cells as a result of the inhibition of mitosis, while in the radioresistant strain the decrease of the A-globulin content reflects the almost unaffected mitosis.

The mechanism of the increase of B-globulins in the radioresistant tumour after irradiation may be more complex and may depend in particular on the accumulation of lipoproteids14. Lipoproteids are highly radioresistant8 and take an active part in the restitution processes.

The relationships between the enhanced radioresistance of tumours and chromosome changes are being widely discussed and data are contradictory. Repeated irradiation both in vivo and in vitro of Ehrlich ascites tumours

followed by intraperitoneal inoculation has revealed a continuous increase in cells with low chromosome numbers. while the stem strain shows a trend towards a decrease in chromosome number.

Our control Ehrlich strain is a hyperdiploid with a stem line of cells containing forty-six chromosomes and very few polyploid forms. When repeatedly irradiated in vivo the stem strain contained chiefly cells with forty-four chromosomes beginning from the forty-sixth passage (Fig. 7), while in vitro a similar stem strain was obtained from the thirtieth passage with a dose of 900-1,000 r., and from the eleventh passage with a dose of 2,000 r. In both cases no significant changes in the number of polyploid forms were observed.

A similar tendency to accumulate cells with low chromosome numbers also takes place after repeated irradiation of ascites ovarian tumours in rats. Thus it seems that the characteristic of developing radioresistance is not the polyploidy but an increase in cells with low chromosome numbers.

MICROBIOLOGY

DNA Homology of Two Mycoplasma **Species**

RECENT work has involved classifying bacteria according to their DNA base composition and homology (for example. ref. 1). This work has used the hybridizing techniques^{2,3} developed for hybridizing RNA with a DNA of high molecular weight which was immobilized in an agar gel. An attempt has also been made to determine whether there is any homology between the DNA of two mycoplasma species, Mycoplasma gallisepticum and Mycoplasma gallinarum, and the DNA of a bacterium Haemophilus gallinarum4. Evidence was presented which demonstrated the reversion and transformation of avian mycoplasmas to H. gallinarum⁵ but no DNA homology was found. Neither could DNA homology be demonstrated between the DNAs isolated from $Streptococcus\ MG$ and Mycoplasmapneumoniae-another pair of organisms which have been suspected of being genetically related -although the two DNAs had similar base compositions. follows is a report of an attempt to determine whether two mycoplasma species, Mycoplasma mycoides variety capri and Mycoplasma laidlawii, are genetically related.

The organisms from the cultures used—the identity and purity of which were confirmed by the appropriate cultural, chemical and serological tests by Dr R. H. Leach (Central Public Health Laboratories, Mycoplasma Reference Laboratory)—were M. mycoides variety capri

P.G. 3 (obtained from Dr D. G. ff. Edward, Wellcome Research Laboratories) and M. laidlawii 545B (obtained from Dr P. Pease, Department of Bacteriology, University of Birmingham). They were grown in the media previously described7,8 and, to obtain DNA labelled with carbon-14, 2^{-14} C-thymidine (20 $\mu c./l.$ of medium) was added. The DNA from the two organisms grown in the non-radioactive and radioactive media was isolated and purified as previously described7.8. The yield (mg/l. of culture medium) and specific activities for the DNA samples isolated were: M. mycoides variety capri DNA, 2.8 mg/l., <0·1 c.p.m./µg; M. mycoides variety capri DNA-14C, 2·7 mg/l., 411 c.p.m./µg; M. laidlawii DNA, 1·1 mg/l., <0·1 c.p.m./µg; M. laidlawii DNA-14C, 1·2 mg/l., 44</p> c.p.m./µg. The base composition of the samples is given in Table 1.

Table 1. BASE CONTENT (MOLES/100 NUCLEOTIDES) OF DNA ISOLATED FROM M. mycoides var. capri AND M. laidlawii

	Adenine	Gua- nine	Cyto- sine	Thy- mine	Guanine + cyto- sine (%)
M. mycoides var. capri DNA	37·8	12·7	12·3	37·2	25·0
M. mycoides var. capri ¹⁴ C-DNA	38·0	12·5	12·7	36·8	25·2
M. laidlawii DNA	33·4	15·8	16·7	34·1	32·5
M. laidlawii ¹⁴ C-DNA	33·5	16·0	16·5	34·0	32·5

The labelled DNA preparations were sheared in an ultrasonic disintegrator (Measuring and Scientific Equipment Limited) until their molecular weights, as determined by sedimentation, were about 300,000. The nonradioactive DNAs were denatured and trapped in agar as described by McCarthy and Bolton³ and the hybridization between this and the denatured labelled DNA was performed according to their method. Hybridization was also attempted between the mycoplasma DNAs and calf thymus DNA in order to check whether any nonspecific hybridization was taking place. Pure Clostridium welchii DNA (ref. 9) was also trapped in agar and hybridization attempted between this and mycoplasma DNAs, because Cl. welchii DNA has a base composition similar to M. laidlawii DNA. The results are given in Table 2.

Table 2. DEGREE OF DNA HOMOLOGY

Radioactively labelled DNA (30 µg)	DNA trapped in agar $(300 \mu g)$	labelled DNA bound (aver- age of two de-	Percentage of labelled DNA bound, relative to homologous hybridization	Percentage of guanine + cytosine of DNA
M. mycoides var. capri P.G. 3	Calf thymus M. mucoides	1.6	5-2	42.0
capit r.c. s	var. capri	31.0	100.0	25.0
	M. laidlawii	5.0	16.2	37.5
	Cl. welchii	2.5	8.1	31.0
	Agar blank	1.2	4.0	-
M. laidlawii 545B	Calf thymus M. mycoides	1.0	2•8	42.0
	var. capri	7.0	18.9	25-0
	M. laidlawii	37·0	100.0	32.5
	Cl. welchii	2.6	7.0	31.0
	Agar blank	0.5	$\mathbf{i} \cdot \mathbf{\check{z}}$	

The results show a limited amount of heterologous hybridization between species of mycoplasma, but several factors have prevented any attempt to show whether this is more than that expected from non-specific hybridization. The DNAs of the mycoplasma species investigated all have extreme adenosine+thymine compositions. Presumably the more extreme the DNA composition, the more non-specific hybridization will be found to occur. The DNAs of the mycoplasma species used here differ in their guanine+cytosine content by 7.5 per cent and thus one would not expect heterologous hybridization to be very high. Sueoka has shown that a difference of 10 per cent in the guanine+cytosine content of the DNAs from two bacterial species indicates that they have few DNA molecules in common because of the unimodal distribution and narrow range of guanine+cytosine content which bacterial DNAs have been shown to possess¹⁰. It was not possible to obtain DNA in sufficient quantity or labelled with carbon-14 from two mycoplasma species which had DNAs with similar base contents. The homologous hybridization of the DNAs used is

rather low. Whether this is because the hybridization had to depend on chiefly adenine-thymine base pairs or whether it is the result of other factors is not known, but it necessarily increases the uncertainty with which the heterologous hybridization results can be interpreted. Moreover, the amount of labelled thymidine which was incorporated into M. laidlawii DNA was not very high but, however, the figures do serve to confirm the trend noticed for the hybridization involving the labelled DNA from M. mycoides variety capri which shows a significant increase for the heterologous hybridization compared with the hybridization obtained with a nonrelated bacterial DNA with a similar base composition.

I thank Dr A. S. Jones for his advice and Mr E. T. J. Chelton for assistance.

Removal of Microbial Pollutants from Waste Effluents by the Redbeard Sponge

RECENT studies1 have shown that the redbeard sponge (Microcionia prolifera Verrill), a common inhabitant of the Atlantic shorelines, is able to use bacteria, notably E. coli, as food organisms. Sponges effectively filter these bacteria out of the sea water and concentrate large quantities of them in their bodies before digestion. The filtering capacity of the sponge was found to depend on the initial concentration of bacteria present in the surroundings, and it was shown that the more bacteria present, the more efficiently the sponge utilizes them. This suggests that the redbeard sponge can be used to combat microbial pollution in estuaries coming from faecal contamination.

In a recent series of papers²⁻⁵, it has been shown that lower fungi like Candida albicans not only survive if exposed to sea water but retain their viability and infectivity to mice almost indefinitely in this environment. This suggests that the seas could be a reservoir for the dissemination of these potentially harmful organ-Because of this, we undertook a study (to be published) to see whether or not redbeard sponges would also use Candida albicans or Cryptococcus neoformans as food organisms, and thus remove these pathogens from the marine environment. These studies indicated that the sponges are able to ingest and utilize these lower fungi in the same fashion as the E. coli in our earlier experiments. Our in vitro studies have shown what seems to be chitinolytic activity in the sponge tissues which effectively lysed the fungal cells. Because all these studies were performed in laboratory conditions, using artificial inoculationsthat is, cultures of bacteria or fungi-before further extrapolations could be carried out as to the effectiveness

of the sponges in the abatement of pollutants, it was necessary to test the effect of some waste effluents known to contain a large microbial population. For this reason, effluents originating from duck farms were selected because they are notorious for their large content of E. coli and other microbes. Our experiments and results on the purification of untreated duck farm wastes by the sponges are presented in this paper.

The localities of collection, the picking of the sponges, the cleaning procedures employed and the maintenance of the animals, were the same as described earlier1. The sponges were manually cleaned of gross contaminating organisms and were kept in glass, non-toxic bonded 10 gallon aquaria containing 19.2 l. of water at constant

temperature (12° C) under constant aeration.

Untreated duck farm effluent was collected at the Carman River Duck Farm, New York, in polyethylene containers. The pH of the effluent was 6.4 at 16°C and its salinity 10 p.p.t. The amount of E. coli was immediately determined. After complete mixing, standard serial dilutions of the duck farm offluent were made using a buffered diluent, and selected dilutions were processed through a 'Millipore' filter apparatus. After filtering, the 0.45 micron filters were placed in 'Millipore' Petri dishes on the surface of sterile absorbent pads soaked with 'M-Endo Broth MF'6. This procedure was repeated for two subsequent trials. All the Petri dishes were incubated at 37°C, and, after 24 h, colonies which exhibited the typical E. coli-like appearance were counted on each set of plates and then averaged to give the number of E. coli cells/ml. of duck farm effluent.

Quantities of the duck farm effluent ranging from 500 to 2,000 cc were added to the aquaria each containing approximately 3.5 lb. wet weight of sponges. Four aquaria without sponges served as controls to test for the inherent bactericidal activity of the sea water7,8. The final concentrations of E. coli in the different aquaria (organisms/cc) are shown in Table 1. The same table

^{*} As a result of the buffering action of sea water (pH 6-8) the drop in pH caused by the addition of DFE (pH 6-4) is negligible. DFE, Duck farm effluent.

shows the salinity values obtained in terms of electrical conductivity measurements performed after the effluent was added to the aquaria. The changes are proportional to the dilutions. Every 24 h for 6 days samples were taken from the water surrounding the sponges and from the control tanks and E. coli counts were performed as described.

The results of the experiments are compiled in Table 2. It is evident that, as in our original experiments, E. coli originating from the duck wastes multiplied rapidly, but after about 24 h there was a drastic decrease possibly as a result of their uptake and digestion by the sponges. During a period of 5 days the count observed dropped from 174 million to approximately 100/cc. In the control experiments, the decrease averaged three orders of magnitude less than in the aquaria containing sponges. earlier observation that the filtering ability of the sponge depends on the concentration of the available microorganisms was again borne out as indicated by comparing the results obtained from tanks 1 and 4, which showed initial counts of 22 and 90 million/cc, respectively. In tank 4 the disappearance of the E. coli was approximately 1.6 times faster than from tank 1 between days 2 and 4 under the same conditions (except for dilution) and at the same sponge weight. The different salinities in these experiments do not seem to be responsible for the faster death rate of the bacteria in the less saline media because the four control tanks did not exhibit such a change. One may therefore conclude that the value mentioned is indeed a real expression of the ability of the sponges to digest greater numbers of bacteria at a rapid rate if quantities of them are available.

The experimental results obtained by using untreated duck farm effluent as a means of introducing food organisms for the sponges do not differ in any essential feature from those of the earlier published data1. Because duck farm effluent probably represents the most noxious type of household or industrial waste, at least in the sense of its high microbial count, the ability of the sponges effectively to clarify such effluents gives further support to the speculation about their possible use as naturally occurring anti-pollution agents. Although these experiments were conducted in laboratory conditions, the use of raw effluent instead of pure cultures is a further step towards the investigation of the sponges in their natural environment.

The dilution tolerance of these animals seems to be quite high and, indeed, the maximal values were not reached. In view of this, it seems reasonable to state that a relatively small mixing of the sewage with sea water would be required if sponges are to be used for microbial decontamination purposes. Sponges could be grown on dykes in the estuaries where sewage effluents enter. The animals would then possibly filter out the bacterial contaminants and the water passing through their bodies would be free of micro-organisms. In addition, the sponges

DFB, Duck farm effluent.

would not only eliminate contaminating microbes from their environment but they would also remove organic matter from the seas. Most of the bacteria entering the estuaries are killed gradually by the toxic effects of sea water and their subsequent decomposition eventually leads to the organic enrichment of the water. If they are taken up by the sponge, however, a high proportion of their material is directly utilized by the animals to build up their own bodies, thus eliminating some of the constituents of the organic load presented by the microbes. These factors indicate the importance of further studies, which should be conducted in actual field conditions to ascertain the long range feasibility of utilizing the redbeard sponge for the control of microbial pollution.

We thank Mr Lloyd Robinson, owner of the Carman River Duck Farm, for his co-operation.

BIOCHEMISTRY

Differential Response of Protein Synthesis in Ehrlich Ascites Tumour Cells and Normal Thymocytes to 2,4-Dinitrophenol and Oligomycin

RECENT work with intact yeast¹ and bacterial cells² suggested that some step in protein synthesis requires energy in a form similar to or identical with the high energy intermediates of oxidative phosphorylation rather than ATP directly. We present here data which indicate that a similar energy form is used for some phase of protein synthesis by intact mammalian cells, such as the thymic lymphocyte. The same requirement, however, cannot be demonstrated for a highly undifferentiated neoplastic cell -the Ehrlich ascites tumour cell (ATC). This alteration in the way in which metabolic energy is usually coupled to protein synthesis may represent the loss of an important control mechanism for regulating protein synthesis in this tumour cell.

The rationale for the experimental approach used in this study is the same as that described for yeast cells1. This can be summarized as follows: if uncouplers (2,4dinitrophenol) or blockers (oligomycin) of oxidative phosphorylation inhibit protein synthesis without affecting the intracellular concentration of ATP in anaerobic conditions when ATP is derived exclusively from glycolysis, some step in protein synthesis must require a high energy form similar to or identical with the high energy intermediates of oxidative phosphorylation.

Ehrlich tetraploid ascites tumour cells given by Dr H. G. Hempling, maintained by weekly intraperitoneal inoculations of 0.2 ml. of a 1:5 dilution of ascitic fluid, were collected 7-10 days after inoculation, and isolated by

centrifugations four or five times at 400 g for 3 min in a wash medium (0.01 molar tris, 0.004 molar potassium phosphate, 0.14 molar sodium chloride, 0.02 molar potassium chloride, pH 7.4) to remove debris and erythrocytes. The cell density was adjusted to give a final concentration of 3 mg of protein/ml. of incubation medium. Thymic lymphocytes were prepared as detailed by Eisen et al.3 from 50-70 g male Wistar rats; cells were diluted to give a final concentration of 0.2 mg of protein/ml. of incubation medium.

Anaerobic incubations were performed by preincubating cells at 37° C with glucose in a 95 per cent nitrogen-5 per cent carbon dioxide atmosphere for 15-30 min before the addition of the inhibitors and isotopically labelled substrates. The incubation medium consisted of 0.04 molar tris, 4 mmolar potassium phosphate, 0.088 molar sodium chloride, 0.02 molar potassium chloride, 2 mmolar magnesium chloride, 2.6 mmolar sodium bicarbonate and 0.66 mmolar glutamine, pH 7.4. The rate of incorporation of ¹⁴C-leucine into cell protein was taken as a measure of protein synthesis. Samples were prepared for counting by adding 0.2-0.3 ml. volumes of the cell suspensions taken at various time intervals to 2-3 ml. of 10 per cent trichloroacetic acid (TCA), filtering on membrane filters with a pore size of 0.45μ, washing three times with 5 per cent TCA, then three times with ether. Isotopic counting was carried out in a Nuclear-Chicago gas-flow counter or a Packard liquid scintillation counter. Rates of incorporation were calculated from the slope of curves of the c.p.m./mg of protein versus time. Protein was determined by the technique of Lowry et al.4 using bovine plasma albumin as standard. ATP was measured fluorometrically as described by Lowry et al.5 on perchloric acid extracts of cell suspensions.

No 14C-leucine was incorporated into protein by either ATC or thymic lymphocytes incubated anaerobically without glucose and there was an increase of about threefold in lactate production in the presence of glucose, thus confirming the completeness of anaerobiosis in this system. In agreement with the original report of Rabinowitze, ATC incubated anaerobically with glucose incorporated ¹⁴C-leucine into protein at 40-60 per cent of the rate in aerobic conditions.

Table 1. Effects of 2,4-dinitrophenol and oligomycin on incorporation of $^{14}\mathrm{C}\text{-LBUCINE}$ into protein and on concentrations of atp in THYMIC LYMPHOCYTES

	incorporation of ¹⁴ C-leucine (c.p.m./ mg of protein × min ⁻¹)	(mμmoles/mg of protein)
Control	6.310	13.32 ± 1.03
2.4-DNP (10-6 molar)	3,170	9.57 ± 3.13
Oligomycin (0.025 µg/mg of protein	3,470	11.50 ± 1.58
2,4-DNP (10-6 molar) + oligomycin (0-025 ug/mg of protein)	1.980	$10 \cdot 10 \pm 2 \cdot 33$

¹⁴C-Leucine was added at 0-667 µc/ml. and had a specific activity of 275 mc./mmole. Five samples were taken in duplicate during 30 min of incubation, and from these rates of incorporation were determined. Experiments were performed anaerobically in the presence of 15 mmolar glucose. Concentrations of ATP were measured in triplicate at 20 min and represent the mean attended deviction. tstandard deviation.

In lymphocytes, 2,4-DNP (10-6 molar) inhibited the anaerobic incorporation of 14C-leucine into protein by about 50 per cent and oligomycin (0.025 μg/mg of protein) impaired protein synthesis by 50 per cent (Table 1). The two agents together caused a multiple effect as if acting on subsequent steps. This would be expected from their actions on ATPase systems and supports the concept that ATP must be changed into some other high energy form before use. The same concentration of oligomycin added to cells incubated aerobically without glucose completely blocked protein synthesis, suggesting interference with mitochondrial ATP production and subsequent inhibition of all extra-mitochondrial energy de-Our studies of isolated fat cells pendent reactions. (unpublished work) confirm these observations on lymphocytes. In contrast to the results noted with thymocytes and fat cells, neither 2,4-DNP (2×10^{-4} molar) nor oligo-

Table 2. Refects of 2,4-dinitrophenol and oligomycin on incorporation of 14 c-leuginh into protein of ehrlich ascites tumour cells

Experiment	; Inhibitor	Incorporation of Control (c.p.m./mg of p	Inhibitor
$\begin{smallmatrix}1\\2\\3\end{smallmatrix}$	2,4-DNP (10^{-4} molar)	1,955	1,922
	2,4-DNP (2×10^{-4} molar)	2,180	1,980
	Oligomyein ($3 \mu g/ml$.)	2,500	2,500

Cells were preincubated in an atmosphere of nitrogen with 15 mmolar glucose as described in the text. The 14 C-leucine was added at 0.3 μ c./ml. and had a specific activity of 4.68 mc./mmole. Five samples were taken during 30 min of incubation, and from these rates of incorporation were calculated.

mycin (3 µg/mg) had any detectable effect on incorporation of 14C-leucine into protein by ATC in anaerobic conditions in the presence of glucose (Table 2).

The data concerning concentrations of ATP in the two cellular systems indicate that the effect of 2,4-DNP and oligomycin on protein synthesis in lymphocytes is not secondary to alterations in concentrations of ATP (Tables 1 and 3). Although oligomycin and 2,4-DNP affect concentrations of ATP to about the same extent in both cellular systems, protein synthesis was affected only in the lymphocytes. The degree of inhibition of this protein synthesis bore no relation to the alterations in the concentration of ATP. Furthermore, there was no additive effect of the two agents on ATP in lymphocytes although a multiple inhibition on protein synthesis was found. Aerobic concentrations of ATP in both the ATC and lymphocytes were in the same range as in anaerobic conditions, showing that glycolysis could maintain normal concentrations of ATP. The ATP data from ATC agree with those of Hempling' on the same cells.

Table 3. EFFECTS OF 2,4-DINITROPHENOL AND OLIGOMYOIN ON CONCENTRATIONS OF ATP IN EHRLICH ASCITES TUMOUR ORLLS

•	mµmoles/mg of prot
Control	34.30 ± 1.07
Oligomycin (3 µg/mg)	$27 \cdot 15 \pm 2 \cdot 11$
2.4-DNP (10-4 molar)	23.20 ± 5.32

Experimental conditions were as in Table 2. ATP was measured at 30 min and represents the mean value of four samples ± standard deviation.

All metabolic processes in mitochondria known to use high energy intermediates of oxidative phosphorylation as energy sources seem to be membrane oriented events; these include reversal of electron transport⁸, ion transport⁹ and protein synthesis10. The conclusion that high energy intermediates of oxidative phosphorylation are involved in these systems is based on the inhibitory effects noted with such agents as 2,4-DNP and oligomycin. Recently, it has been shown that 2,4-DNP and oligomycin sensitive ATPases are not restricted to the mitochondrial membrane but are also present in both plasma¹¹ and microsomal membranes12.

In view of these considerations, it is tempting to interpret the original studies in yeast1 and bacterial cells2 and this study on lymphocytes and fat cells as an indication that some step in protein synthesis in the intact cell is coupled to an ATPase system which is membrane localized and sensitive to DNP and oligomycin. This system functions by converting ATP to another high energy form before use in this step. The lack of effect of these inhibitors on protein synthesis in the ascites tumour cell suggests either a loss or alteration of this step which is dependent on a high energy intermediate in this neoplastic cell. defect is unlikely to reside in an alteration of the membrane localized ATPase system, for Hempling' has shown that sodium and potassium transport in this ascites tumour cell can be inhibited by both DNP and oligomycin in conditions when ATP is supplied exclusively by glycolysis. Rather, it seems that the protein synthetic process itself has been modified so that it can use ATP directly and is no longer dependent on the membrane localized ATPase system. Consistent with this interpretation are the observations of Barbieri¹³ that in normal liver incorporation of amino-acids by membrane bound ribosomes was much greater than that of free ribosomes, whereas in a hepatoma strain the reverse was observed.

Effects of Various Substances on DNA Synthesis in Guinea-pig Skin in vitro

In studies of healing and cell replication in the epidermis. attention has been directed chiefly towards mitosis and the factors controlling it1-9. In the guinea-pig, however, the earliest evidence of an injury response is an increase in the number of cells synthesizing DNA, which can be detected as soon as 4 h after injury¹⁰. Peaks of mitotic activity occur later (24-48 h) and injury seems to impose a temporary synchrony on cell division in the epidermis. so that successive waves of DNA synthesis followed by mitoses take place. Although small peaks of mitotic activity were recorded at about 18 h, Sullivan and Epstein¹¹ showed that the main burst of mitotic activity in humans occurred between 42-60 h.

Bullough⁴⁻⁶ has suggested that the injury response is mediated through a tissue specific antimitotic "chalone" which is neutralized by injury. There is no evidence. however, that this tissue extract is inhibitory to DNA synthesis; and on the other hand, Hell (unpublished observation) has produced evidence of a tissue extract which will stimulate cells to synthesize DNA. In view of the time relations of DNA synthesis and mitosis, it would seem more important to study the former. Accordingly, a range of substances was tested in vitro for their ability to affect the proportion of cells synthesizing DNA. The method used was that of Hell and Cruickshank¹⁰. injured epidermal slices were cut free-hand from the dorsum of the guinea-pig ear and floated on a culture medium (horse serum 40 per cent, Hanks BSS 60 per cent) containing tritiated thymidine. The substance to be tested was added to some cultures and an equal volume of SNS was added to the controls. After incubation for 4 h the skin slices were fixed and sectioned and autoradiographs were prepared according to the method of Pelc12. Two thousand cells were counted in each sample and the percentage of those engaged in DNA synthesis was recorded in the slices with and without additives. The substances were chosen because they were known to be released during injury, or because they were known stimulators or inhibitors of mitosis.

Of the substances tested, no effects were observed with insulin (0.5 mg/ml.), histamine (0.5 mg/ml.) or adrenaline (0.1 mg/ml.). It was found, however, that serotonin (5-hydroxytryptamine) had a distinct stimulating effect

Table 1. SEROTONIN (5-HYDROXYTRYPTAMINE)

Exp. No.	Control Mean % positive	Ser	5 mg/ml. otonin % positive Mean difference	Ser	mg/ml. otonin % positive Mean difference
$\frac{1}{2}$	5·0 2·9	$\frac{7 \cdot 2}{3 \cdot 7}$	$^{+2\cdot2}_{+0\cdot7}$	8.0	+3.0
$\frac{2}{3}$	7·1 3·8	9·4 4·3	+2·3 +0·5	10.9	+3.8
4 5 6	6·9 4·5	10·0 7·7	+3·1 +3·2	9.3	+2-4
7 Averages	5·9 5·1	$8.3 \\ 7.2$	$+2.4$ 2.1 ± 0.38	7∙9 8∙5	$^{+2.0}_{2.8\pm0.39}$

For 0.15 mg/ml. t=5.5, P>0.01 (significant). For 0.3 mg/ml. t=7.2, P>0.01 (significant).

on DNA synthesis (Table 1). The magnitude of this effect after incubation for 4 h was only slightly less than that shown¹⁰ to be induced by injury in vivo.

Thus there is evidence that the inhibition of mitosis by adrenaline reported by Bullough³ is not accompanied by an inhibition of DNA synthesis. Similarly the colcemid effect is reflected in scarcely any interference in DNA synthesis13.

Although serotonin has a marked effect on DNA synthesis in vitro, it would be unwise to conclude that it is a significant factor involved in the increased DNA synthesis after wounding in vitro. It is possible, however, that further work on the control of the initiation of DNA synthesis might be more rewarding than the study of mitosis in the investigation of wound healing.

Metabolic DNA in Heart and Skeletal Muscle and in the Intestine of Mice

STUDIES of the incorporation of labelled thymidine into the DNA of heart muscle and skeletal muscle in adult animals have shown significant values which indicate regular renewal of some or all of the DNA in these non-dividing organs^{1,2}. Autoradiography has shown labelled muscle nuclei in smooth muscle and in heart muscle and therefore subsidiary cells, such as lymphocytes, cannot be held responsible for the labelling. The existence in plant materials of two separable fractions of DNA with different rates of turnover has been shown by Sampson et al.3, and Sampson and Davies have presented good evidence for the location of a fraction (DNA1) with a high rate of turnover in differentiating cells and of a stable fraction (DNA2) in meristematic cells of Vicia faba. The results of experiments designed to compare the specific activities of the DNA fractions with a molecular weight below 4×10^6 with those above 4×10^6 in heart, skeletal muscle and intestine are reported here.

Adult male mice of strain BALB/c (25-30 g) were injected intravenously with 60 µc. of tritiated thymidine

(specific activity 17 c./mmole, obtained from CEN, Mol). The mice were killed by cervical dislocation 12, 24 and 48 h after injection and the organs—heart, muscle and intestine-were dissected and frozen in dry ice.

The DNA was extracted from the different organs by a method previously described⁵. After homogenization in a saline solution of EDTA in an 'Ultraturax' blender and the addition of sodium lauryl sulphate, the extract was digested with pronase. The nucleic acids were precipitated with alcohol and redissolved in saline EDTA. The solution was treated with RNase and then with pronase. The DNA was precipitated with alcohol and redissolved in saline citrate.

About 500 µg of DNA obtained from different organs was fractionated by chromatography on DEAE cellulose paper⁵. Using discontinuous elution, fractions containing DNA molecules of different molecular weights were recovered. It has been shown that degradation of DNA is not the cause of the appearance of fractions with a low molecular weight. The amount of DNA per fraction was estimated by ultraviolet spectrophotometry, and the radioactivity of the different fractions was estimated on a Packard liquid scintillation counter.

Comparison of the results from the fraction with a molecular weight between 5×10^5 and 4×10^6 (I) with that of a molecular weight above 4×10^6 (II) is shown in Table 1. The specific activity of the molecules of the first group is obviously higher than that of the second group in the three organs. This observation proves again⁶ that the fractions of lower polymers are not the products of degradation of the higher polymer fractions. The (adenine+thymine)/(guanine+cytosine) ratio in mammals is 1.4:1. If the low polymer DNA (I) had an unusually high ratio, say 5:1, the specific activity of fraction I would be only 1.6 times that of fraction II. It can be concluded that differences in the (adenine+ thymine)/(guanine+cytosine) ratios cannot explain our findings, although a correction may be necessary.

Table 1. Specific activity of heart, muscle and intestinal dna after injection of tritiated thymidine

	I	II	I/II
		Adult mice	
Heart	5∙6	0-4	14
Muscle	16-0	1.1	14.6
Intestine	55-7	12.1	4.6
		Young mice	
Heart	6.5	1.2	5.4
Muscle	15.7	2.0	7.8
Intestine	61.5	19.0	3.2

Intestine of 5 19 19 19 3.2 I. Specific activity (d.p.m. $\times 10^{-4}/\mu g$ DNA) of molecular weight of DNA $5\times 10^{4}-4\times 10^{4}$, fractions 4-7. II: Specific activity (d.p.m. $\times 10^{-3}/\mu g$ DNA) of molecular weight of DNA above 4 × 10°, fractions 9-12. I/II: ratio of the specific activities of fractions 4-7 and 9-12. The results for adult mice at various times after injection were pooled; young mice (18-20 days old) were killed 24 h after injection. Taking the amount of DNA in fractions 4-12 as 100 per cent, the metabolic DNA (I) represents 43 per cent in heart, 30 per cent in skeletal muscle and 36 per cent in intestine.

The ratio of the specific activities (I/II) is 14:1 for muscle and 4.6: 1 for intestine. If all labelling of DNA in the intestine were the result of synthesis in preparation for mitosis, a ratio of 1:1 would be expected. The observed ratio of 4.6: I suggests that DNA turns over in some cells in this organ. Disregarding a possible correction for differences in the (adenine + thymine)/(guanine + cytosine) ratios, it would have to be assumed that of the total labelling with tritiated thymidine in the intestine about 25 per cent represents labelling of DNA in cells which are not proceeding to mitosis and 75 per cent is the result of pre-mitotic DNA synthesis. Accurate determinations of the relative number of labelled crypt cells and labelled non-mitotic cells are not available, but preliminary counts do not disagree with this estimate. Up to 6 per cent of the cells are labelled in the lamina propria of the small intestine, where divisions are not seen; in addition labelled nuclei can be found in the smooth muscle surrounding the organ.

The specific activity in the low molecular weight fraction (I in Table 1) is very similar for adult and young mice, while that for fraction II is considerably higher for young animals, which implies some proliferation in the

muscles of young mice.

The high specific activity in the low molecular weight fraction, especially in the non-dividing muscles, can be explained by the assumption that metabolic DNA exists as a separate fraction in mammalian cells and that the average molecular weight of this fraction is relatively Metabolic DNA represents 36-43 per cent of the total DNA scored in our experiments (Table 1). present it is not known whether metabolic DNA is necessarily and permanently in the low polymer form. The evidence for metabolic DNA in mammalian tissues presented here is in accord with that for plant tissues by Sampson et al.3 and by Sampson and Davies4.

Effect of Cholesterol on the Water Permeability of Thin Lipid Membranes

In order to assess the relative importance of the various membrane constituents in determining the water permeability of thin (<100 Å) lipid membranes^{1,2}, have conducted a series of experiments in which the concentrations of the individual components, particularly cholesterol, in the membrane forming solutions have been varied. The osmotic permeability coefficients, P_f , of membranes formed from the solutions given in Table 1 were determined as described before3.

Table 1. COMPOSITIONS OF MEMBRANE FORMING SOLUTIONS Amounts of lecithin and cholesterol in 1 ml. of solvent with tetradecane* mg of lecithin mg of cholesterol Cholesterol: lecithin #

^{*} The solvent was tetradecane: chloroform: methanol in the volume proportions 18:48:32,
† The solvent was chloroform: methanol in the volume proportions 2:1,
with 200 mg of tocopherol added per ml. of chloroform methanol.
‡ Average molecular weight of lipids was taken as twice that of cholesterol.

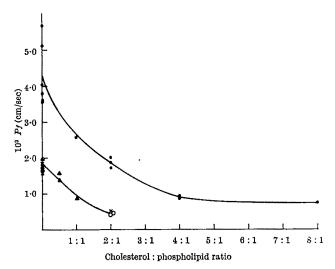

Fig. 1. P_f as a function of molar ratio of cholesterol: phospholipid. All films were formed at $36^{\circ} \pm 0.01^{\circ}$ C by the technique of Mueller et $al.^{1-2}$ in solutions of either unbuffered 100 mmolar sodium chloride or of 100 mmolar sodium chloride + 0.2 mmolar magnesium sulphate + 5 mmolar histidine (pH = 7). After the membrane had become completely black, the concentration of sodium chloride was increased on one side and the rate of water movement was determined. The "mixed lipid" was extracted from ox brain white matter by the method of Mueller et al.' twice split with water to remove protein, and passed through a "Unisil" column to remove cholesterol. • Lecithin membranes formed with tetradecane as the additive; \times , "Mixed lipid" membranes formed with tetradecane as the additive; \wedge , "Mixed lipid" membranes formed with ergosterol as the additive; \wedge , "Mixed lipid" membranes formed with ergosterol instead of cholesterol. (Both tetradecane and dl-atocopherol were present as additives.)

Fig. 1 shows the values of P_f , obtained in independent experiments, as a function of the molar ratios of cholesterol to phospholipid in the membrane forming solutions. The phospholipids were egg lecithin or "mixed lipid" from ox-brain white matter. We found that (a) for both types of membranes the water permeability decreases with relative cholesterol concentration, in lecithin films falling from $4\cdot 2\times 10^{-3}$ cm/sec without cholesterol to $0\cdot 75\times 10^{-3}$ with 8:1 cholesterol: phospholipid, and in "mixed lipid" films, falling from $1\cdot 8\times 10^{-3}$ to $0\cdot 49\times 10^{-3}$ with 2:1 cholesterol: phospholipid; (b) at any given cholesterol concentration, P_f of legithin membranes is consistently larger than P_f of "mixed lipid" membranes (c) P_f is not significantly dependent on the additive (that is tetradecane or dl-atocopherol) used.

We have succeeded in forming several membranes from solutions of the egg lecithin sample after it had been completely hydrogenated. P_f was 1.7×10^{-3} cm/sec, which is approximately 2.5 times less than that of membranes formed from the original partially unsaturated sample.

The knowledge that cholesterol lowers the water permeability of thin lipid membranes is relevant to understanding the mechanism of water transport across them. Hanai and Haydon⁴ have pointed out that the size of P_f is consistent with a simple solubility-diffusion mechanism; that is, at each interphase water partitions (in proportion to its mole fraction in the aqueous phases) into the hydrocarbon region of the membrane, and diffuses through the hydrocarbon region under the concentration gradient thus If this mechanism is operative, then P_f should be sensitive to changes either in the solubility of water or the diffusion coefficient of water in the membrane.

To see whether these factors can reasonably explain the cholesterol effect, we have conducted experiments on bulk hydrocarbons. Assuming that the phospholipids, through their polar groups, and cholesterol, through its hydroxyl group, are anchored at or near the water interface, we have chosen as a model for the hydrocarbon region of the membrane either hexadecane or 1-hexadecene for the phospholipid contribution and cholestane for the cholesterol contribution. The viscosity of a cholestane: 1-hexadecone solution of molar ratio of 1:3 (corresponding in our membranes to a cholesterol: phospholipid ratio of 2:3) was found to be twice that of 1-hexadecene alone. Thus the effect of cholesterol on water permeability can be attributed to an increase in the viscosity of the hydrocarbon region, which produces a proportional decrease in the diffusion coefficient of water within this phase.

It might be possible that chloroform or methanol trapped in the film controls the water permeability, and that cholesterol somehow reduces their concentrations. We have, however, obtained comparable results with membranes formed from mixtures of lecithin and cholesterol dissolved in decane (no chloroform : methanol present), so that this possibility seems to be excluded. It might also be suggested that cholesterol decreases the water permeability by significantly increasing the membrane thickness. Hanai et al. have shown, however, that the electrical capacitance of these membranes increases when cholesterol is added, which suggests a decrease in membrane thickness. In any case, barring tremendous effects of cholesterol on the dielectric constant, this observation indicates no significant increase in thickness.

In addition, we have compared the viscosities of hexadecane and 1-hexadecene, and the solubility of water in these two hydrocarbons. The viscosity of hexadecane is 12 per cent greater than that of hexadecene, while the water solubility is 15 per cent smaller. (Solubilities were determined by the static equilibration method using tritiated water. We checked our method by measuring the solubility of water in benzene and tetradecane; our values agreed with those of Schatzberg'.) Both effects suggest a smaller water permeability of a saturated lipid membrane relative to that of an unsaturated one, and this was observed. More relevant would be comparable data for 8-hexadecene cis, the double bond of which is centrally positioned as are the double bonds in the phospholipids, but this material is unavailable.

It is a priori both hazardous and naive to attempt quantitative comparisons between the properties of bulk hydrocarbon and those of films less than 100 Å thick. The proportion of cholesterol in the films may be quite different from that in the membrane-forming solutions; furthermore, the meaning of "viscosity" in a 100 Å film is not obvious. Nevertheless, the parallel between the properties of the bulk hydrocarbon and the thin membrane is very suggestive. With this solubility diffusion model, the polar ends of the molecules constituting the membrane play no part in determining the value of P_f . The differences we have found between "mixed lipid" films and lecithin films may argue against this, but until comparisons are made between phospholipids with different polar heads but identical hydrocarbon tails, no conclusion can be definitely drawn.

That the water permeability of thin lipid membranes is dependent on cholesterol content may be of physiological relevance. The ubiquity of cholesterol or related sterols (we have obtained a similar decrease in P_f with ergosterol (see Fig. 1)) in plasma membranes of all organisms other than bacteria and its scarcity in some intracellular membranes is well known, but the physiological function of cholesterol in membranes is not understood. It would be interesting to know if there is any correlation between the values of P_f of biological membranes and their cholesterol content; such data are still unavailable. We note, however, that the mucosal membrane of toad bladder epithelial cells is much less permeable to water than the serosal membrane⁸ and that 'Amphotericin B', a polyene antibiotic that seems to interact specifically with sterol containing membranes, affects the mucosal membrane but not the serosal10.

Proton Conductors in the Respiratory Chain and Artificial Membranes

Many chemical compounds can uncouple electron transfer from energy accumulation in the respiratory chain. Uncouplers stimulate electron transfer in conditions in which the rate of oxidation is limited by coupled phosphorylation. The precise mechanism of uncoupling is obscure.

We have studied the action of uncoupling agents using mitochondria, reconstituted succinate oxidase, artificial phospholipid membranes and solutions of phospholipid in heptane. Rat liver mitochondria were separated in a solution of sucrose 0.25 molar and 0.001 molar EDTA and incubated in a mixture containing 0.25 molar sucrose, 0.02 molar potassium chloride, 0.01 molar potassium phosphate, 0.005 molar magnesium chloride, 0.03 molar tris buffer and 0.002 molar EDTA, pH 7.5. Succinate oxidase was reconstituted from cytochrome c and purified enzyme complexes: succinate-cytochrome c-oxidoreductase and cytochrome c-oxidase. Respiration was measured polarographically, and reduction of NAD and cytochromes by fluorimetry and differential spectrophotometry, respectively.

To prepare artificial bimolecular membranes a solution of brain phospholipid in heptane (10 mg/ml.) was used. The membrane was formed in a hole (diameter of 1-1.5 mm) of a small 'Teflon' vessel with a double wall. The space between the walls was filled with the solution of phospholipid. As a water phase we used the same mixture which was used for the incubation of mitochondria.

Experiments with biological systems gave the following results. (a) All uncouplers, regardless of differences in their chemical structure, have a qualitatively identical effect on mitochondrial respiration in the absence of phosphate acceptor; an increase in the concentration of uncoupler causes the respiration first to be activated and then inhibited. Inhibition was accompanied by the oxidation of NADH and cytochromes^{3,4}. Uncoupling activities are in the following order: p-trifluoromethoxy-carbonyleyanidephenylhydrazone (FCCP) = M-chlorocarbonylcyanidephenylhydrazone (CICCP) ≥ tetrachloro-2-trifluoromethylbenzimidazol (TFB) > dicumarol > 2,4dinitrophenol (DNP) = β -hydroxynaphthoic acid > salicylic acid. (b) The most active uncouplers (CICCP, FCCP, TFB) can stimulate mitochondrial respiration and also inhibit respiration of mitochondria as well as of reconstituted succinate oxidase in amounts equal to or smaller than those of the respiratory enzymes contained in the sample. (c) Inhibition of respiration by uncouplers is competitive with respect to the concentration of oxidation substrate4,5. The affinity of succinate dehydrogenase for the most active uncouplers was found to be many times greater than its affinity for the substrate. Thus the affinity of the reconstructed succinate oxidase system for TFB should be

Table 1. CORRELATION OF THE EFFECTS OF UNCOUPLERS ON MITOCHONDRIAL RESPIRATION AND ON ELECTRIC CONDUCTIVITY OF THE ARTIFICIAL PHOSPHO-LIPID MEMBRANE

Uncouplers	$(C_{1,2})_a$	g at $(C_{1/2})_a$	$(C_{1,2})_i$	g at $(C_{1:1})_i$
DNP	2×10 ⁻⁵ molar	2	5×10^{-4} molar	10
TFB	10 ⁻⁷	2	1.5×10^{-8} ,,	30
FCCP	8×10 ⁻⁸ ,,	3	2.5×10^{-8} ,,	30

 $(C_{1:3})_a$ and $(C_{1:3})_i$ are the concentrations of the uncoupler which cause half maximal activation and half maximal inhibition of mitochondrial respiration, respectively (the oxygen consumption in state 2 was subtracted). Substrate was 0-01 molar succinate. g, Electroconductivity of artificial phospholipid membrane in the presence of the corresponding concentration of the uncoupler; the electroconductivity of the membrane without uncoupler $(3 \times 10^{-3} \, \text{mho} \times \text{cm}^3)$ was taken as a unit.

105-106 times greater than that for succinate. Inhibition by TFB is easily reversible: addition of excess succinate to succinate oxidase after TFB stimulates respiration to the same extent as succinate added before TFB.

These data demonstrate considerable differences between uncouplers and other enzyme inhibitors. The latter: (a) are very specific in relation to their structure; (b) act in quantities not less than those of the enzymes; (c) usually have less affinity for the enzymes than does the substrate, if inhibition is reversible and competitive.

We have investigated possible causes of the unusual action of the uncouplers in model systems. In experiments with artificial bimolecular phospholipid membranes, we confirmed the data of Bielawski, Tompson and Lehninger⁶ regarding the decrease of the electric resistance of the membrane after addition of DNP. Other uncouplers have a similar effect. The effectiveness of the compounds studied in the membrane systems correlates with their effects on mitochondria (Table 1). In natural as well as in artificial systems the strongest uncouplers (FCCP, CICCP, TFB) were four orders of magnitude more active than the weakest one (salicylate); DNP occupies an intermediate position.

The increase in electric conductivity of the membrane caused by uncouplers was a result of the increase in the selective permeability of the membrane to hydrogen ions.

Experiments with solutions of the uncouplers in heptane showed that uncoupling agents (UH) may dissociate by the equation $UH \rightleftharpoons U^- + H^+$ in a hydrophobic system, if phospholipid is added. This is indicated by the characteristic changes in the absorption spectra of uncoupler in heptane after addition of phospholipid (DNP and TFB are studied). The hydrogen ions provided by uncoupler in heptane medium can protonate the nucleophilic groups there. This effect is easily demonstrated by the red staining of the heptane layer after the addition of the uncoupler to the mixture of heptane, phospholipid, methyl red and water. The data of the physical and chemical experiments suggest that the actions of the uncouplers in the biological system are a result of the provision of protons to the hydrophobic part of the enzyme structure.

Considering the uncouplers not as enzyme poisons but as catalysts for hydrogen ion transfer in the hydrophobic medium, the unusual characteristics of the uncouplers can easily be explained. The non-specificity of the chemical structure of the uncouplers is quite understandable if, in the system UH ⇌ U- + H+, the H+ ions are an active part, and U functions chiefly as a mobile proton carrier in the hydrophobic medium.

It can be shown that substitution of the only hydrogen atom in the TFB molecule with a methyl group prevents uncoupling activity (see ref. 7) and decreases the inhibitory action of this substance on respiration. Dinitrobenzene neither uncouples oxidation in mitochondria nor increases electroconductivity in the artificial membrane system.

The ratio [uncoupler] < [enzyme] is also explained by the catalytic character of the action of the uncoupling agents. The stoichiometry [H+]: [enzyme] > 1 is always fulfilled in the experimental conditions because of the buffer capacity provided by the components of the incubation mixture. It is also clear that the unusually high affinity of the enzyme for the uncoupler may only be apparent if the function of the uncoupler is to provide H+. In this case,

it is not necessary for the active centre of the enzyme to contact with UH or U-.

The mechanism of uncouplers as proton donors was first considered by Mitchell's. Mitchell's chemiosmotic concept of coupling predicts a correlation between the respiratory activation effect of the uncoupler and its effect on proton conductivity of the membrane. According to Mitchell's scheme the lipid soluble proton carrier decreases the membrane potential, which is supported by the respiratory chain and is necessary for energy transformation8,9

Another explanation of the uncoupling effect of hydrogen ions10 could be that H+ competes for nucleophilic intermediate $(X^{\delta^{-}})$ in coupling mechanisms with the electrophilic energy carrier $(Y^{\delta^{+}})$. H+ ions might also cause acid hydrolysis of the primary high energy compound $X \sim Y$.

Competitive inhibition of purified dehydrogenases by the uncoupler may be explained by protonation of enzyme groups responsible for attachment to the substrate. In the absence of uncoupler these groups are protected from H+ ions of water by the hydrophobic parts of enzyme or bound phospholipid. Protonation of the dehydrogenase functional groups can be assumed to demand the greater concentration of H+ ions in the hydrophobic medium than protonation of $X^{\delta-}$ (or $X \sim Y$). The uncoupling therefore precedes inhibition of respiration in the course of increasing the concentration of the proton donors. It is interesting that an uncoupler inhibits mitochondrial respiration and reconstituted succinate oxidase respiration as well. The second system differs from the first in lacking the organized membrane structures although it contains phospholipids. Thus the effect of uncouplers as proton conductors is not limited by their action on the membrane.

We thank Drs A. V. Babakov, A. A. Jasaitis, E. N. Mokhova, V. P. Topali and L. S. Yagujinsky for their help and Drs L. Büchel and L. Wojtczak for some of the uncouplers.

Optical Clearing Effect of Dextran on Human Platelet Suspensions

THE optical density of platelet-rich citrated plasma or of platelet suspensions has been seen to decrease irreversibly on the addition of a solution of dextran1. This decrease is biphasic, consisting of an immediate optical clearing effect independent of the molecular weight of the dextran fraction but related to its final concentration, and a delayed effect affected by molecular weight². Because certain dextran fractions induce aggregation of human platelets¹, it was at first assumed that the decrease in optical density of platelet-rich citrated plasma was caused by aggregation¹. Only the delayed changes in optical density, however, seemed to correspond to the degree of platelet aggregation evaluated microscopically after the addition of dextran². The immediate optical clearing effect of dextran has been further examined with a turbidimetric method and re-interpreted in the light of additional work on the optical properties of dextran.

Platelet-rich citrated plasma was prepared as previously described. Platelet suspensions in saline-trishydrochloride were made according to Haslam's method. Platelet aggregation was graded microscopically according to the scheme proposed earlier, and the glassware used was siliconized. The optical density of platelet-rich citrated plasma and platelet suspensions was measured with an EEL titrator using a red (608) filter. Twenty per cent solutions of dextrans of various mean molecular weights (10,000–500,000) were prepared in 0.9 per cent sodium chloride. Refractive indices of solutions of dextran, human albumin and polyvinyl pyrrolidone in 0.9 per cent sodium chloride were measured for a range of concentrations from 0.5 to 20 per cent with an Abbé refractometer.

Solutions of dextran were added to 2 ml. samples of platelet-rich citrated plasma to give a final concentration of 1.8 per cent, and the change in optical density was recorded. Three samples from each cuvette were examined microscopically without delay by an observer unaware of the additive or of the change in optical density, and the degree of aggregation was graded. Despite approximately equal turbidimetric changes with various fractions, the microscopic findings showed pronounced differences. Using similar methods it was found that several antagonists of platelet clumping inhibited aggregation by dextran in relatively low concentrations but had no effect on the immediate reduction in optical density. Thus the optical clearing effect of a material known to aggregate human platelets could not be ascribed entirely to aggregation. Furthermore, human albumin showed a similar optical effect on platelet-rich citrated plasma and platelet suspensions, yet we found no microscopic evidence of aggregation by albumin even in high concentrations.

It is known that changes in optical density of suspensions can also occur from alterations in optical properties at phase boundaries. The quantitative relationship between turbidity and refractive index (the Rayleigh–Gans equation)⁵ as applied to a platelet suspension is as follows:

$$\frac{\tau}{c} = \frac{4\pi\alpha^3}{\lambda} \cdot \frac{d_{12}}{d_2} \left(\frac{m^2-1}{m^2+2}\right)^2 \times 10^{-2}$$

where τ is turbidity; c is "concentration" of platelets; α is $\pi D/\lambda$, a parameter of D, the diameter of the platelets; λ is wavelength of the incident light; d_{12} is the density of the suspension with the additive and d_2 the density of the suspension without the additive; m is μ/μ_0 where μ is the refractive index of the platelets and μ_0 that of the medium. The wavelength of the incident light, λ , was constant. Thus,

$$\frac{\tau}{c} = K' \frac{d_{12}}{d_2} \left(\frac{m^2 - 1}{m^2 + 2} \right)^2$$

and because the ratio d_{12}/d_2 will not change appreciably, then

$$\tau = K'' \left(\frac{m^2 - 1}{m^2 + 2}\right)^2$$

Simplifying further,

$$\frac{\tau}{c} = K'' \left(\frac{\frac{\mu^2}{\mu_0^2} - 1}{\frac{\mu^2}{\mu_0^2} + 2} \right)^2 = K'' \left(\frac{\mu^2 - \mu_0^2}{\mu^2 + 2\mu_0^2} \right)^2$$

Because the change in $(\mu + 2\mu_0^2)$ will be small, then to a first approximation

$$\frac{\tau}{c} = K (\mu^2 - \mu_0^2)^2$$

It should be noted that $\tau=0$ when $\mu=\mu_0$. Thus if the immediate optical clearing effect of dextran is the result of changes in the refractive index of the suspension, K should be constant for all dextran fractions.

The refractive index of platelets in *tris* hydrochloride buffer was found by titrating a platelet suspension with dextran 40. In the titration plot the dextran concentration axis can be interpreted as a refractive index axis and thus the intercept on this axis $(\tau=0)$ gives the value for μ . Extrapolation of the linear part of the curve gave a value of 1.3772. This value is closely similar to the platelet refractive index found with a similar titration using human albumin. The values of K (Table 1) were then calculated from data derived from turbidity changes of a platelet suspension with different concentrations of dextran.

The effect of dextran 10 (molecular weight 10,000) concurred with the Rayleigh-Gans equation at all concentrations. The higher molecular weight fractions (that is, molecular weight 80,000 and more) also accord with it at low concentrations despite microscopic evidence of slight platelet clumping. The optical phenomenon described may therefore prevent detection by optical means of minor degrees of platelet clumping. An increasing departure from the Rayleigh-Gans equation, however, was observed at concentrations of dextran greater than 2 g/100 ml. (Table 1). At such concentrations, even in artificial media free of bivalent cations, pronounced platelet clumping occurred with the higher fractions and was detectable optically.

	Table 1.	VALUES O	F K	
Final dextran concentration (g/100 ml.)	D10†	D40	D80	D 500
1.8	3,105	3,050	3,035	3,020
3.3	3,150	3,007	2,990	2,475*
4.6	3.280	2.980	3,060	1,936*
5.7	3,300	2,925	2,940	1,470*
6-6	3,190	2.685*	2,790*	1,152*
7-5	3.175	2,415*	2,295*	745*
8-2	3,090	2,205*	2,090*	589*

Values were calculated from the experimental data derived from turbidity changes of a human platelet suspension in saline *tris* hydrochloride medium with different final concentrations of dextran. Further details are given in the text

* Calculated values of the constant K which do not concur with the Rayleigh-Gans equation.

† D10, dextran with a mean molecular weight of 10,000; D40, dextran with a mean molecular weight of a0,000, and so on.

Thus the immediate optical changes caused by dextran result from changes in the refractive index of the medium. This reasoning was additionally supported by the finding that the turbidity of platelet suspensions could be reduced almost to zero by raising the refractive index of the medium to that of platelets with other colloids such as polyvinyl pyrolidone or human albumin. Because the refractive indices at any given concentration of a series of polymer fractions are known to be constant this interfacial phenomenon explains the observed independence of the immediate optical clearing effect of the molecular weight of dextran¹.

Thus, although platelet clumping by dextran in vitro is not disputed, our earlier interpretation of its immediate optical clearing effect was in error and our conclusions regarding the relationship between molecular weight and clumping activity were inaccurate. Furthermore,

it is clear that optical properties of the examined materials should be considered when Born's method6 is used to measure platelet aggregation.

APPLIED SCIENCE

Wind Forces and the Proximity of Cooling Towers to Each Other

A REPLY1 to a letter written by Malik and myself2 on cooling towers and drag forces contains an error to which I wish to draw attention.

Our letter reported some measurements of drag forces on spheres supported in assemblages through which a fluid was constrained to flow. The measurements were represented as the variation of the drag coefficient for a single sphere in our assemblage with the particle Reynolds number, and the well known relationship for the isolated single sphere was included in the graphs as a comparison. Unfortunately, Bearman misread the results as the drag coefficient for unit projected area across the whole assemblage, and quoted a simple application of Torricelli's law to show that our results could be explained by consideration of momentum changes in an ideal fluid. As the assemblage was twenty layers deep, a twenty-fold error was generated, so that Bearman's table for the drag coefficient related to unit projected area for the assemblage should read

	T	s	
a	S	R/eU^{2} (measured)	$\frac{2(1-S)^{s}}{\text{(predicted)}}$
0 0·5 1·0	0·785 0·349 0·197	146 5·0 2·8	8·5 0·41 0·15

...

It would have been surprising if such a theory were to describe the results of the complex fluid-solid interactions found in flow through assemblages of solids, although one could produce a better agreement than that shown in Table 1 by reformulating the assumptions in the light of the experimental results.

We have since published a full account of our experimental results3.

In the latter part of his letter Bearman suggested that our inferences concerning the increase of drag forces on objects caused by proximity did not apply to objects in unconstrained airflow. This is a point which merits some discussion because the proper resolution may be useful in designing experiments to give reliable drag coefficients for groups of bodies.

It is a matter of common experience that in conditions of unconstrained airflow around groupings containing large numbers of bodies, the hydrodynamic resistance of the bodies can so resist penetration of air flow that drag forces on bodies in the centre of the grouping may be very small. For example, conditions inside a forest are still, even in strong winds. Shallow groupings, however, such as the Ferrybridge cooling towers, are much more susceptible to wind penetration, and it is certainly possible

that the difference between drag coefficients measured in constrained and unconstrained conditions of airflow will be small at lateral spacings similar to the cooling towers, although one acknowledges that the difference will increase sharply for very small lateral separations. There is some experimental evidence of increase in drag coefficients of the order of 50 per cent for a sphere in proximity to one other in conditions of unconstrained flow4.

Wind penetration into shallow groupings of bodies will also be affected by the scale of turbulence of the atmospheric flow field (or the distance over which the field is correlated). If the distance over which the flow field is correlated is comparable with, or smaller than, the dimensions of the grouping, one would expect a degree of wind penetration rather greater than found during steady flow.

A further effect of unsteady flow comes to mind from the extensive work of Lunnon⁵, who investigated drag forces on spheres accelerating through fluid. He found that the force acting on an accelerating body was greater than that experienced by the same body in steady conditions at the same velocity, the difference increasing with acceleration.

The report of the committee of inquiry⁵ attributed most of the blame for the failure of the Ferrybridge cooling towers to structural weakness arising from a misinterpretation of the results of wind tunnel tests on isolated towers. Wind tunnel tests on groupings of towers were commissioned, and one may calculate from the table on p. 10 of the report the ratio of drag forces experienced by tower 1A (in the centre of the grouping) to that experienced by an isolated tower as $(84\cdot3/74\cdot6)^2=1\cdot28$, an increased force that is obviously significant particularly when it is borne in mind that but for the diversionary effect of the station buildings on the wind flow the measured increase would probably have been larger.

The results of wind tunnel tests can presumably be relied on to be accurate indications of real conditions only if the conditions measured are related to atmospheric turbulence. In the absence of specific wind tunnel tests on groups, the remarks on wind penetration into groups of bodies suggest that it is not unreasonable to assess the effects of proximity of bodies, in such groups as the Ferrybridge cooling towers, as though the flow were constrained. The results of our experiments show that at interbody spacings similar to that of the Ferrybridge group one would expect an increase in drag forces because of proximity of about 90 per cent-probably something of an overestimation, yet perhaps not very different from the increase that would be experienced by a central tower in a Ferrybridge group without the station buildings.

Intensive Beef Production from Molasses and Urea

An important problem in many underdeveloped countries is the shortage of protein, particularly animal protein. This is rarely because the animal population is small, but rather because of the poor productivity which results from the dependence on forages and pastures characterized by low energy availability.

In most developed countries extensive methods are being superseded by intensive systems based to an increasing degree on high energy (grain) diets; but underdeveloped countries have neither the economic resources to buy grains nor, at the present time, the necessary technical skills to grow them on a large enough scale. Many underdeveloped countries in tropical areas, however, do have an abundant source of readily available energy in the form of sugar cane. Much of this energy is exported in the form of sugar and molasses, often at low profitability. If means could be found to exploit this energy source as an alternative to grain, more intensive systems of animal production could be developed with obvious economic and social benefits.

Supplementation of pasture with molasses has tended to give disappointing results; for example, in Brazil, Mott et al. giving 2 kg of molasses daily to grazing Zebu steers increased gain by only 0.08 kg/day. In Cuba, addition of urea to the molasses produced better results than molasses alone, but overall performance remained low2. The feeding of fresh Napier grass supplemented with molasses and urea to 247 Zebu bulls in dry lot gave an average daily gain of 0.56 kg with an energetic efficiency of 41.7 Meal of metabolizable energy/kg of gain. This can be compared with a daily gain of 0.97 kg and an energy conversion of 18-8 Mcal/kg for eighty similar bulls given grains and molasses and urea freely (unpublished work of T. R. Preston and M. B. Willis).

Lofgreen³ found that increasing quantities of molasses in a mixed diet were utilized with decreasing efficiency, while others4.5 have demonstrated that large amounts of sugar (as in molasses) depress the digestibility of cellulose. It seemed that the apparent incompatibility of feeding forage and molasses together might best be resolved by reducing the forage to the minimum level commensurate with normal rumen function.

A randomized block experiment was carried out with forty-eight Zebu bulls weighing, on average, 244 kg. They were housed in groups of three on slatted floors. All were given 1.5 kg of green forage maize/100 kg live weight/day and had free access to an aqueous solution of sugar cane molasses (14 per cent soluble solids) containing 0.67 per cent urea. A mineral mixture containing large quantities of phosphorus and sodium was also freely available*. Half the animals were given a protein-mineral-vitamin supplement; at the rate of 200 g/100 kg live weight/day. The other half received a similar supplement, but diluted with an equal part of ground maize and fed at the rate of 400 g/100 kg live weight/day. The feeding period was 168 days and feed allowances were adjusted every 14 days in accordance with live weight. Samples of rumen liquor were taken by stomach tube from all animals half way through the trial. These were analysed for pH, volatile fatty acids and ammonia and counts of bacteria and protozoa were made. The bulls were slaughtered at an average weight of 370 kg and their carcasses dissected according to the procedure outlined by Willis and Preston⁶.

Six animals were removed from the experiment, two because of molasses toxicity, and four because of injuries. The principal results are set out in Table 1.

The most striking features of the work were: (a) an average of 73 per cent of the dry matter and 76 per cent of the total metabolizable energy (calculated) from molasses; (b) an average of 58.6 per cent of the total nitrogen in the form of urea or ammonium sulphate; (c) high daily gains (38 per cent better than with ad libitum forage and molasses-ureas; (d) high killing out percentages (comparable with grain-fed cattle and 13 per cent better than with forage3); (e) an energy conversion only slightly poorer than that with grain and 41 per cent better than with forage3; and (f) conditions in the rumen resembled those of animals being given large amounts of forage and differed markedly from those usually associated with high energy diets (for example, pH 6.8 \pm 0.4; steam volatile fatty acids 93 ± 25 m.equiv/l., ammonia $4.63 \pm$ 3.43 m.equiv/l., and a large and varied protozoan population, particularly Flagellates, Entodinium and Isotrichs).

These findings thus present a new pattern. Gains, feed conversion, killing out percentage and the content of ammonia in the rumen closely resemble those obtained with Zebu cattle feeding on grain, while carcass composition, rumen pH and rumen flora and fauna are similar to those of animals feeding on large quantities of forage3. The concentration of volatile fatty acids in the rumen is remarkably low in view of the high energy intake.

Table 1. MEAN VALUES FOR WEIGHT GAINS, FOOD CONSUMPTION AND CARCASS COMPOSITION FOR BULLS COMPLETING THE TRIAL

	Supplement/100 kg live weight 200 g +			
Item	200 g	200 g maize	S.E.*	
No. of bulls Initial weight (kg) Final weight (kg) Daily gain (kg) Daily gain (kg) Green maize Molasses Supplement Minerals Conversion of metabolizable energy (Meal/kg gain) Killing out percentage Carcass composition (per cent) First quality meat	22 236 355 0·72 1·10 5·28 0·41 0·06 25·2 57·0 29·0	20 252 386 0.83 1.19 5.11 1.06 0.08 24.5 56.2	± 9·0 ± 0·12 	
Total meat Excess fat	73·2 8·7	72·6 9·2	± 0.52 ± 0.62	
Bone	18•1	18.1	± 0.68	

^{*} There were no significant differences between supplements.

Of the nitrogen intake, only 10.6 per cent comes from true protein (fish meal, yeast and grain), while 58.6 per cent is derived from urea and ammonium sulphate, the balance being 19.8 per cent from molasses (the nitrogen of which is predominantly non-protein) and 11.0 per cent from forage. Such a high level of non-protein nitrogen has only been used previously with purified diets without, however, the level of feed utilization and performance recorded here. The usual recommendations are that such synthetic sources of nitrogen should not exceed 25-30 per cent of the total nitrogen8,8.

Three hundred bulls are now involved in experiments designed to develop further this feeding system.

BOOK REVIEWS

CHEMISTRY OF BRAIN ACTIVITY

Molecular Basis of Some Aspects of Mental Activity Edited by Otto Walaas. (Proceedings of a NATO Advanced Study Institute held at Drammen, Norway, August 2–14, 1965.) Vol. 1: Pp. xv+476. (London: Academic Press, Inc. (London), Ltd.; New York: Academic Press, Inc., 1967.) 110s.

This is the first of two volumes which contain the proceedings of the NATO meeting. It carries twenty-eight contributions which vary greatly in their quality and in

their relation to mental phenomena.

The mental activities to which its introduction and opening papers are oriented are those of learning and memory, approached first in terms of a particular model system. O. Hechter and C. E. Robinson have sought to apply current concepts of nucleic acid and protein metabolism to develop a theory of memory and recall. This merits serious consideration, although its present support comes largely through analogies to information transfer in genetic systems. The account of directly related experimental work is not convincing; after a subsequent paper "Facilitation of Learning in Rats by Intracisternal Injection of RNA from the Brain of Trained Rats", the recorded discussion displays appropriate scepticism. Other contributions, however, are related in illustrating the importance of protein metabolism to the brain, in giving details of protein synthesis in bacterial and tumour cells, and in describing protein interactions which can condition the growth of neural systems.

Subsequent sections concern inherited metabolic errors, with accounts of phenylketonuria and galactosaemia, the mechanism of hormone action, and biologically active amines. These include valuable accounts of cyclic 3,5-adenosine monophosphate specifically in relation to neural systems; indeed, the mammalian brain is the richest known source of enzymes forming and degrading the cyclic phosphate. Accounts of serotonin and noradrenaline illustrate electrophysiological and pathological approaches to mental phenomena, and an account of the retina and visual pathway contributes an anatomical viewpoint. Some contributions claim no specific relationship to mental activities, such as those describing lactic dehydrogenase isoenzymes and glutaminases, and Cori's excellently factual account of the phosphorylases of liver, muscle and potato. Nevertheless, substrates of the dehydrogenase, glutaminase and phosphorylase, as they operate in the brain in vivo, include compounds which change in concentration with changed cerebral activities.

Discussion sections follow most of the papers and add much to the value of the book; it also carries author and subject indexes.

H. McIlwain

INTRACELLULAR MEMBRANES

Intrace'lular Membraneous Structure

Edited by S. Seno and E. V. Cowdry. (Proceedings of the First International Symposium for Cellular Chemistry at Ohtsu, March 27-31, 1963.) Pp. xix+588. (Okayama, Japan: Japan Society for Cell Biology, 1967.) n.p.

FOR many purposes cells have been conveniently regarded as bags of enzymes surrounded by a selectively permeable membrane. Enzyme studies began by homogenization to obtain a solution or suspension for assay; flux studies assumed that the cell interior behaved as a single undivided compartment. This concept was, of course, a simplification; even before the development of the electron microscope, subdivisions of the cell interior were obvious. Since then a wealth of detailed information has been gained concerning the structure and function of cell organelles. It is a striking fact that many of these organelles consist of membranes arranged in a complex and specific manner; and it is becoming increasingly clear that their functions depend essentially on the character and arrangement of the membranes.

The symposium recorded in this volume brought together electron microscopists, cytochemists, cell physiologists and biochemists, so that there is a full treatment of each topic. The important cellular membranes are dealt with in turn: endoplasmic reticulum, mitochondria, Golgi complex, nuclear membrane and plasma membrane. The standard of the individual papers is very variable, ranging from some masterly reviews of the latest research (such names as Fawcett, Green, Sjöstrand, Novikoff, Robertson and Holter speak for themselves), to some rather disappointing papers, which review older work or are largely speculative. There are also many interesting accounts of more detailed experimental work, mainly by

Japanese authors.
Perhaps the weakest section is the final one on transport processes through membranes. Three of the most interesting papers are not really relevant to the subject: a discussion of the role of moving membranes in active transport relies on morphological evidence, unsupported by the quantitative data which are essential in this field; and a paper on cellular water is best described in the words of the author—"All this, and more, is pure speculation". In this section only the interesting paper of Onoé and Ohno on fat absorption can be regarded as a contribution to knowledge of membrane transport.

Minor defects are frequent misprints and poor English. Some of the reviews also suffer from the delay of four years in publication, which may be connected with the tragic death of two of the Japanese conveners shortly after the conference.

In spite of its defects, the coverage of this symposium is unique and the volume is highly recommended reading for those interested in cell biology. The volume is dedicated to the late Dr Seizo Katsunuma.

D. A. T. DICK

YEAST PROTOPLAST SYMPOSIUM

Symposium über Hefe-Protoplasten/Symposium on Yeast Protoplasts, Jena, 21 bis 24 September 1965 (Abhandlungen der Deutschen Akademie der Wissenschaften zu Berlin, Klasse für Medizin, Jahrgang 1966, Nr. 6). Herausgegeben von Rudolf Müller. Pp. vi+ 430. (Berlin: Akademie-Verlag, 1967.) 61.50 D.M.

It often seems that research on yeasts is pursued less actively than on other groups of micro-organisms, for only occasional papers appear in the commonly read microbiological journals. It is therefore a pleasant diversion to find a symposium almost entirely devoted to yeasts. Fifty-one papers are included, of which thirty-three are in English and eighteen in German, with English summaries. Many of the papers have only a tenuous connexion with the subject of yeast protoplasts; eight of the papers are not even concerned with yeasts. The volume offers, however, a very thorough coverage of recent yeast research, especially in the countries of Eastern Europe. The papers are grouped in five sections: microscopic and submicroscopic structure of yeast protoplasts (eight papers), structure and biosynthesis of yeast cell walls (thirteen papers), physiological and biochemical

studies on yeast protoplasts and isolated structures (ten papers), protoplasts of other organisms (seven papers) and studies on intact cells of yeasts and other organisms (thirteen papers). The opening lecture, a survey of trends in yeast research by J. R. Villanueva, is a particularly inspiring review of recent work on the yeast cell wall, including studies on protoplasts and regeneration of cell wall material.

The title is therefore rather misleading; although various aspects of the biochemical activities of yeast protoplasts are discussed, there is no indication of the large proportion of papers concerned mainly with the cell walls of yeasts, with protoplasts achieving only incidental mention. Electron microscopical studies, chemical structure and biosynthesis of the glucan, mannan and peptide or protein components are discussed many times, and the question of chitin-is it or is it not present ?-is revived. Anyone interested in these topics need not be deterred by the specialized title; he will find the book a valuable addition to his library. There is an additional bonus—by collecting contributions from many authors whose papers are normally prepared only in Russian, Czech or in other Eastern European languages, and presenting findings in English or German, a wider range of recent yeast research work is available to those of more limited linguistic ability.

All illustrations and tables are collected as an appendix of 135 pages. The standard of presentation of this section is excellent and the figures and tables referring to any particular paper are easily located. Apart from the index pages and editorial foreword, the text of the book has been produced by offset lithography from typescript. At approximately £5 the book is rather poor value for money in spite of the large number of photographs. Also, why must it have a soft paper cover, and why, in view of the supposedly rapid method of printing, has it taken almost two years since the symposium for the book to appear?

I. CAMPBELL

BIOCHEMISTRY OF PLATELETS

Biochemistry of Blood Platelets

Edited by E. Kowalski and S. Niewiarowski. (Colloquium held on the Occasion of the Third Meeting of the Federation of European Biochemical Societies, Warsaw, April 4-7, 1966.) Pp. vii+191. (London: Academic Press, Inc. (London), Ltd.; New York: Academic Press, Inc.; Warsaw: PWN-Polish Scientific Publishers, 1967.) 45s.; \$8.

This book contains eleven papers in English and two in French, presented at a colloquium held in Warsaw in April 1966. As so often with the published versions of scientific meetings, one wonders whether the delay of more than 12 months before publication is not too high a price to pay for the eventual elegance of production. A few of the contributions are essentially review articles, but most include accounts of original work; some of this has already been published elsewhere since these papers were delivered, but workers in the field will be glad to have them collected in a compact volume. The value of the book is considerably enhanced by the inclusion of the discussion after each paper, and by a comprehensive subject index; the value of the author index is less

The contributions cover many aspects of platelet biochemistry, including nucleotide metabolism (Holmsen; Spaet and Lejnieks), clotting factors (Deutsch; Niewiarowski), aspects of the "release reaction" (Kowalski; Markwardt), and biochemical abnormalities occurring during storage (Caen) and in congenital platelet disorders (Gross). Mustard discusses the relation of platelet haemostatic function to platelet turnover, Kopeć and her colleagues the effect of fibrinogen degradation products

on platelets, and Davey and Lüscher the protein constituents of platelets. Platelet immunology and ultrastructure are the subjects of papers by Salmon and Libánská respectively. Much active research is continuing on all of these aspects, and this volume is best regarded as a progress report, rather than as a general survey of platelet biochemistry. As such, it will be of interest chiefly to those actively engaged in the field.

R. M. HARDISTY

CHROMOSOME DAMAGE IN MAN

Human Radiation Cytogenetics

Edited by H. J. Evans, W. M. Court Brown and A. S. McLean. Pp. 218. (Proceedings of an International Symposium held in Edinburgh, October 12–15, 1966.) (Amsterdam: North-Holland Publishing Company, 1967.) 70s

This volume is one outcome of a technical advance which has made it possible for chromosomal damage in particular human somatic cells to be studied in considerable detail. In essence, the break-through is the use of phytohaemagglutinin (PHA) to stimulate cultured peripheral blood lymphocytes to go into mitotic division, so that the metaphase chromosomes of large numbers of cells can be scrutinized after appropriate colchicine and hypotonic pretreatments. From the contributed papers and the very short summary of unpublished discussion it is clear that there is now general agreement on methodology. In particular, it has now been realized that the previously preferred sampling time of seventy-two hours after culture initiation gives erroneously low estimates of chromosome damage; fifty hours is now favoured. This agreement is important, because divergent views on optimum fixation times have undoubtedly contributed to the markedly different results obtained in different laboratories. Unfortunately, however, large and puzzling discrepancies still remain.

The first group of papers is concerned with fundamental studies (mainly by H. J. Evans and co-workers) on the mechanics and dynamics of the leucocyte culture system and on the dose-response kinetics of exchange aberrations induced by both X-rays and fast neutrons at different dose rates. Considerable differences were found between these chromosomes and those of higher plants in their radiation response. Altogether, this group of contributions provides a very useful foundation for further work and for the interpretation of in vivo results.

Many subsequent papers describe such in vivo studies on populations exposed in one way or another to excess ionizing radiation. Although some reports are preliminary it is already obvious that this new approach is reaping rich dividends, chiefly in greatly increased knowledge of the nature, extent and persistence of chromosomal damage after both acute and chronic irradiation. Valuable new information has also been gained on the life span and immunological behaviour of the lymphocyte. The possible use of this technique for accurate biological dosimetry and for the detection of other mutagenic agents besides radiation is also discussed.

Full exploitation of this technique for population studies demands the removal of a bottleneck, namely, the time taken to detect and analyse each suitable mitotic cell. It is appropriate, therefore, that two papers should deal with possibilities of automating this process. The problems involved and the solutions advocated are dealt with lucidly and at length, making it clear that the difficulties are not insuperable and that success is only a matter of time.

To the receptive reader this volume should prove as stimulating as PHA to a lymphocyte.

A. G. SEARLE

AFRICAN NECTAR DRINKERS

The Sunbirds of Southern Africa; also the Sugarbirds, the White-Eyes and the Spotted Creeper

By C. J. Skead, assisted by Cecil M. Niven, J. M. Winterbottom and Richard Liversidge. Pp. 351+22 plates+gramophone record. (Cape Town and Amsterdam: A. A. Balkema, 1967. Published for the Trustees of the South African Bird Book Fund.) Rs. 8.50.

This is the second of a series of monographs dealing with certain groups of birds as represented in Southern Africa. It emanates largely from the Percy Fitzpatrick Institute of African Ornithology attached to the University of Cape Town, and its publication is sponsored by the South African Bird Book Fund. It gives a systematic account of the species of four passerine families of the Old World tropics and subtropics, three of them having in common the habit of drinking flower-nectar; two are represented in the area by single genera, puzzling in their taxonomic relationships.

The sunbirds (Nectariniidae) are represented by twenty species and their treatment thus occupies the larger part of the volume. Sunbirds correspond ecologically to the hummingbirds of the New World; and they likewise show brilliantly coloured plumages, well illustrated here by John Perry. Of the white-eyes (Zosteropidae) there are just three representatives, the main concentration lying further to the east. The genus Promerops is peculiar to the area and has two species; it is commonly placed among the honeyeaters (Meliphagidae), otherwise an Australasian family, but in this work judgment is reserved by keeping it in a family of its own. The rather inapt name "sugarbird" probably relates to the remarkably close association between the birds and the Protea bush, suikerbos in Afrikaans. The spotted creeper, of the small genus Salpornis, shows resemblance to the treecreepers (Certhiidae) but is usually regarded as an aberrant nuthatch (Sittidae); it has a slender decurved bill, like the sunbirds and sugarbirds, but is not a nectar drinker.

There is a general review of each family, after which the species are treated separately under such headings as local names, distribution in South Africa and elsewhere, field characters, habits, habitat, food, voice, breeding and taxonomy. In addition to the ten colour plates and twelve plates of photographs, there are line drawings illustrating breeding techniques, courtship attitudes and the like; and there are maps showing distribution in Southern Africa. In a pocket at the back there is a small two-sided gramophone record of sunbird calls and songs, edited by June Stannard. The book is well arranged and attractively produced. In all, a great deal of both old and new information has been usefully put together in convenient form.

LANDSBOROUGH THOMSON

CATALOGUE OF NYCTERIBIIDS

An Illustrated Catalogue of the Rothschild Collection of Nycteribiidae (Diptera) in the British Museum (Natural History)

By Oskar Theodor. Pp. viii + 506 + 5 plates. (Publication No. 655.) (London: British Museum (Natural History), 1967.) 360s.

THE dearth of comprehensive articles on the systematics of Nycteribiids is rectified by this outstanding and essentially monographic opus, which presents a revision of the family as a whole. The number of taxa described as new to science is: one subfamily (of a total of two), one genus (of eight), one subgenus (of nine), thirty-seven species (of 189) and two subspecies (twelve non-nominate).

After discussing and illustrating the complex morphological characters used in the taxonomy of Nycteribiids, the technical terms are defined in a special glossary which

The cites figure references for further clarification. systematics of the various taxa are then presented and the differential characters summarized in table form. names and authors of all species treated are listed. Dichotomous keys to these genera, subgenera, species and subspecies usually employ multiple and alternative diagnostic characters, cite page and figure references, and The taxonomic at times include geographic notes. section resembles in format the laudable system of the companion volumes on Siphonaptera by Hopkins and Thus, complete taxonomic citations are Rothschild. given for each taxon, including designation of synonyms, and succinct diagnoses and descriptions are presented, together with notes on hosts and distribution (supplemented by six maps). The cardinal taxonomic features are illustrated in a set of 898 figures of drawings and nine photomicrographs. Synonyms, misidentifications and major references to valid names can be recognized at a glance in the index.

The figures are clear and illustrate well the characters used in taxonomy. The keys are simple, terse, accurate and sound, and their use is facilitated by the wealth of excellent illustrations. The diagnoses and descriptions are lucid and deal with essential characters, emphasizing why the scheme of systematics employed can confidently be regarded as authoritative throughout.

Despite the complexity of the subject and the innumerable details presented, the book is remarkably free from errors, and in general the volume indicates superior editing and workmanship by the author, by the Hon. Miriam Rothschild and by the staff of the British Museum.

Dr Theodor is to be commended on having prepared a definitive opus which, for the first time, enables the nonspecialist to identify Nycteribiids on a global basis and thereby lays the ground work for much needed research on the habits and bionomics of Nycteribiids and on their possible role as vectors of infection. The volume also contributes to our knowledge of evolution and zoogeography and of the affinities of these parasites and their hosts.

PLANT TERPENES

Terpenoids in Plants

Edited by J. B. Pridham. (Proceedings of the Phytochemical Group Symposium, Aberystwyth, April 1966.) Pp. xi+257. (London: Academic Press, Inc. (London), Ltd.; New York: Academic Press, Inc., 1967.) 70s.; \$12.50.

THE essential oils of plants were among the first naturally occurring materials with which organic chemists concerned themselves. Interest in plant terpenic components and in more complex terpenes from other sources continues unabated and has, indeed, been quickened by the introduction of modern techniques.

The present volume is based on the proceedings of a symposium held under the auspices of the Phytochemical Group in the spring of 1966. The contributions cover a wide field, but it is perhaps a sign of the times that of the twelve chapters seven are concerned in whole or in part with biosynthesis. These include a useful review of methods for the preparation of tritiated and deuterated mevalonate and their application in unravelling the stereochemical course of the biosynthesis of squalene. There are also accounts of the biosynthesis and metabolism of monoterpenes, the in vivo and in vitro skeletal transformations of diterpenes, the biosynthesis of cardenolides, bufadienolides and steroid sapogenins, phytosterol biosynthesis, the biosynthesis of terpenoid quinones and a fascinating review of the variety of sesquiterpenes, mostly derivatives of furan, found in the essential oil of Myoporum deserti A. Cunn. Other chapters are concerned with a discussion of the biological significance of terpenes

in plants, a subject in which interest has been reawakened by the discovery of abscisin and the gibberellins, and accounts of the conformational analysis of terpenes and steroids, structural studies in the carotenoid field (mainly devoted to applications of physical methods), and brief reviews of the chemistry of isoprenoid quinones and of long chain isoprenoid alcohols.

The book will be of greatest value to research chemists and biochemists with a special interest in terpenoid chemistry, for whom it provides authoritative accounts of the position reached in various fields of activity at the beginning of 1966. The level of the contributions is variable, but most are useful and informative. It must be said, however, that the volume remains little more than a disparate collection of short review articles, and one wonders whether publication of books of this type is always really justified. The best articles in this book could just as well, and at less expense, have been published in the ordinary way in review journals, and anyway what is good for a symposium is not necessarily good for a book. A little more discrimination here would have made a better book.

W. Carruthers

ADVANCING STATISTICS

The Advanced Theory of Statistics

By Maurice G. Kendall and Alan Stuart. Vol. 3: Design and Analysis, and Time-Series. Pp. ix + 552. (London: Charles Griffin and Co., Ltd., 1966.) 136s. net.

"This is the final volume of our treatise"; "... we write these final words with a considerable sense of relief". No one can contemplate the 500 pages between these first and last words without profound admiration for the authors and envy of the breadth of their knowledge. Like its two predecessors, this volume is an indispensable work of reference for statisticians whether their primary interests are theoretical or applied. Despite a longer gestation than had been hoped, the work has been kept up to date: the frequency of references dated 1965 or 1966 is high.

The volume divides into three parts. Chapters 35 to 40 are concerned with analysis of variance, Chapters 41 to 44 with the present state of multivariate analysis, and Chapters 45 to 50 with time series. As is inevitable in an encyclopaedic publication, the concise style and concentrated information are not conducive to consecutive reading by a reviewer. A balanced critical discussion of the whole is impracticable; all that can be given here are general comments and discussion of selected details biased towards my special interests.

To a reviewer who believes strongly that statistical theory needs contact with real problems and real observations, the authors' attitude occasionally seems unduly abstract, as in a remark on the avoidance of cross-classifications with one observation per cell. Similarly, a remark about the possibility of covariance analysis when the covariate is affected by treatment surely deserves more critical discussion. On the other hand, a section on the choice of model for analysis of variance is excellent in its insistence on using knowledge of the origin of the observations, and on the relation of design and randomization to the character of inference: "when the observations are not the result of a designed experiment, the validity of the chosen analysis will depend on the insight of the statistician".

In the analysis of variance chapters, the extensive discussion of experimental design and sample survey is valuable, but the distinction is strangely stated: "in surveys we make observations on a sample taken from a finite population of individuals, whereas in experiments we make observations which are in principle generated by a hypothetical infinite population". Sampling perhaps always relates to a finite population, but in some circum-

stances an experiment also may be conducted with reference to a finite population; moreover, the statemen quoted takes no account of the notion of comparison that is inherent in experiments, or of the necessity that the investigator shall decide the allocation of treatments to subjects. A little later, tribute is paid to Fisher's advocacy of randomization: "the most important and the most influential of his many achievements in statistics" the opportunity of reiterating the equally important but slightly different role of randomization in sampling seems to be missed. As the authors well illustrate, the logic of inference from experiments is intimately dependent on the factor structure and the randomization. Tome, however, discussion in terms of "choice of factors to be randomized out" confuses by its seeming implication of deliberate sacrifice of knowledge. In reality, randomization is the protection against ignorance of all the factors in the population that may affect the variate being studied, and the choice important to the experimenter is that of the population of subjects within which he will randomize.

The main categories of experimental design are described briefly, with emphasis on combinatorial structure more than on circumstances of use. A concise matrix presentation of general analysis of variance procedures is of course included. Greater concern for the use of designs might have led to more critical discussion of the consequences of interaction in Latin and higher order orthogonal squares, and of the need for randomization at two levels if inter-block information is to be recovered. The need for fuller study of permutation tests for complicated experiments is strongly argued. This is an issue that statisticians have yet to face fully, instead of accepting the difficulty of the algebra as an excuse for its neglect. Computers may soon make possible the adequate study of distributions underlying the tests of significance, but we must avoid a return to the practice of stressing these to the exclusion of the properties of estimates of para-The sections on lattice and factorial designs meters. scarcely suffice to show their connexions. Moreover, too little attention is paid to the exploitation of confounding and fractional replication in concentrating the information from an experiment on the issues of greatest interest; again the concern seems to be more with combinatorial niceties than with the refining of a research instrument.

As might be expected, the authors are more at home with sample survey, although relative to the major texts on sampling these seventy pages can only outline the theory with little mention of the practical complexities. Thus the reader finds here excellent accounts of procedures for removing or minimizing the purely probabilistic bias of various estimators, but he must go elsewhere for guidance on biases arising from questionnaire design or non-response. Somewhat surprisingly, the special problems of compromise in planning a survey when many variates must be studied simultaneously (as in most real surveys) are scarcely mentioned.

The hundred pages on multivariate statistics summarize well the theory of a subject in which practice has lagged behind theory until the coming of computers. A chapter on the main distributions is followed by an excellent account of types of hypotheses and how they are tested. Three branches of canonical analysis are considered under the headings of component analysis, canonical correlations, and factor analysis; admirable though the text is, the impression remains that much yet remains to be learned of the relations between the three and the parts that each should play in the analysis of data. The final chapter of this part is concerned with discrimination and classification, a field in which objectives are more clearly defined. Though brief, this survey of methods is especially welcome in view of the great current interest in applications as diverse as medical diagnosis and the principles of taxonomy. The systematic presentation of types of classification problems is particularly valuable.

I am not competent to discuss the chapters on time series. An important addition (relative to Dr Kendall's previous volumes) is an account of spectrum theory. A final chapter, recognizing the special difficulties in applying the theory of time series to "real" data, briefly reviews special topics connected with estimation of parameters, testing the adequacy of a fitted model and multivariate series.

In reviewing a book of this magnitude, to pick out particular errors or lapses in clarity is much easier than to evaluate fairly the features that are good but less specific. To say that the three volumes of Kendall and Stuart have weaknesses is in no way a denial of the great achievement they represent. For at least the next ten years, they will occupy a central place in statistical literature; for many years longer, they will be a standard reference. Will these authors, or any others, ever have the courage and skills to produce a new work on even grander scale in 1977?

D. J. Finney

ABSTRACT ALGEBRA

Abstract Algebra

By Andrew O. Lindstrum, jun. (Holden-Day Series in Mathematics.) Pp. xii+211. (San Francisco and London: Holden-Day, Inc., 1967.) \$10.

Most of the topics treated in this textbook of abstract algebra would find a place in courses for honours degrees in pure mathematics in this country at the present time. The author may have attempted to cover too many topics in the space available to him, for the treatment is sometimes rather compressed, particularly in group theory and linear algebra. Much care has been taken, however, in the preparation of the material and many points of detail have received thoughtful treatment.

While the substance of the book is good in many respects and I have a feeling that the lectures on which the book is based were very successful, it does not in its present form seem to be an attractive exposition for an undergraduate reader. He would not read it with the pleasure he should get from such a course, and his interest might not be maintained. He might get used to the abstract and formal style and should make an effort to do so, but the practice of requiring the reader to supply his own proofs of various theorems is overdone. In moderation, the practice can stimulate and encourage a student, but here it might well irritate and depress. This defect of presentation is regrettable because the book has some interesting and commendable features.

The bibliography would have been more useful if it had been related in a more specific way with the various chapters of the book, and if some of the books mentioned were recommended for collateral reading and others for a study of further developments.

H. O. FOULKES

CLASSICAL ANALYSIS

A Second Course in Complex Analysis

By William A. Veech. Pp. ix+246. (New York and Amsterdam: W. A. Benjamin, Inc., 1967.) \$8.75.

VEECH builds on an assumed standard first course in complex variable, dealing with Cauchy's theorem, residues and simple mappings. He then pursues a number of related topics, all of which are now important parts of classical analysis. The style is midway between that of an elementary text and a research memoir, and should prepare the honours student for the reading of periodical literature.

The first four chapters hang very closely together, with a strong geometrical interest. A chapter on analytic

continuation and one on conformal mappings, using the Schwarz lemma and reflexion principle, prepare for the chief theme, the relation between analytical and topological equivalence expressed most simply in the Riemann mapping theorem, here obtained as a corollary to the more general Koebe mapping theorem. In this domain, the language of covering surfaces and covering maps is conveniently employed. Following on this are the results springing from the Picard theorem that an integral function has at most one exceptional value, the Landau and Schottky theorems, Montel's normal families, the Koebe-Faber distortion theorem, Bloch's constant. In this section, modular functions are used but the requisite properties are obtained in the text.

The remaining two chapters are a little detached from the chief theme. One deals with integral functions, deriving the Weierstrass product and the more difficult Hadamard product for functions of finite order. The last chapter discusses the Riemann zeta function and gives Ikehara's proof of the prime number theorem. In mentioning the way in which Landau, Wiener and Ikehara successively minimized the amount of zeta function theory required, the impetus given by the Tauberian theorems of Hardy and Littlewood is not noted.

T. A. A. BROADBENT

ELECTRIC MACHINES

Generalized Electric Machines

By A. J. Ellison. Pp. 146. (London: George G. Harrap and Co., Ltd., 1967.) 20s. net.

Electrical Machines

(Electrical Engineering Series.) By A. Draper. Pp. xx+384. (London: Longmans, Green and Co., Ltd., 1967.) 63s. net.

DURING the past few years a large number of books have appeared dealing with electrical machines. Most of these have been concerned to try to present a "generalized" approach to the subject, beginning with a description of electro-mechanical transducers in either circuit or energy terms and often going some way towards considering the systems in which the transducers are employed.

Of the two books reviewed here, Ellison comes closer to the current fashion. It is a companion volume to the same author's book Electromechanical Energy Conversion. published in 1965; the present book, however, is unique in being wholly concerned with the structure and details of a laboratory course directed at complementing typical modern lecture courses employing a generalized approach. The title, which is thus seen to be somewhat misleading as a description of the subject matter, presumably refers to the special purpose laboratory machines now widely available as vehicles for courses such as those described. The author has contributed much to the development of modern laboratory courses and, in this country, pioneered the first generalized laboratory machine in conjunction with AEI. Material sufficient for a course of up to twelve three hour periods is described, comprising for each experiment an introduction, a description of apparatus and general arrangements, a procedure, an outline of the relevant theory and calculations and a discussion and set of questions for the student. The course described is a good one, as would now, we believe, be generally agreed. But the fact that this agreement largely exists already, raises the question of exactly what need this text fulfils. Experienced teachers will have their own views on courseplanning, and will prepare laboratory sheets which will supersede this book as far as their students are concerned; but it could certainly be of value to younger and less experienced teachers and to those needing persuasion to make a change from a traditional to a generalized laboratory.

The book by Draper is closer to the traditional approach to machine exposition than most of those written recently. This is not to be critical of it, but to indicate that it will meet a need for those who feel that the more fashionable approach is too far removed from practical devices and leaves the student with problems of visualization and appreciation. It is the second edition of the successful book which first appeared in 1956. This new edition follows the same pattern as the earlier one and is improved chiefly by the addition of a chapter dealing briefly with the principles and application of semi-conductor devices; also the treatment of the induction motor has been extended somewhat, and one or two ideas on closed-loop control are included. The treatment of single-phase machines remains brief, and matrix methods, although referred to in the preface, are not seriously exploited; however, both these topics are treated in the author's companion text Electrical Circuits (including Machines), and cross-references are given. The present book is remarkable for the breadth of its coverage—all practically important machines, together with mercury-arc rectifiers, are included, even if briefly. That this should be possible without the treatment becoming unacceptably superficial or scrappy is due to the author's commendably simple and clear style. Because of its coverage and its readability, this book will attract many students.

P. J. LAWRENSON G. W. CARTER

TEXTILE CHEMISTRY

Textile Chemistry
By R. H. Peters. Vol. 2: Impurities in Fibres; Purification of Fibres. Pp. xiii+374. (Amsterdam, London and New York; Elsevier Publishing Company, 1967.)

In the main this book comprises an excellent and detailed description of the industrial chemistry associated with the processes of scouring and bleaching of cotton and other cellulosic fibres. There are chapters on the chemistry, scouring and bleaching of wool, and particularly on the fundamental work on the reactions of wool in aqueous media. There is some reference to man made and regenerated cellulose and its esters, and also to the aqueous reactions of silk fibroin.

The first chapter gives an account of the industrial uses and chemical content and contamination of water from various sources and forms a fitting introduction to the aqueous fibre chemistry which follows. There follows a detailed physico-chemical study of sequestering agents and co-ordination compounds. The bearing of this subject on dyestuff absorption is obvious, and in the next chapter ion-exchange phenomena are discussed with a strong mathematical accent on sorption and swelling properties of fibres. The fourth chapter is a rather short description of some of the natural fibres; possibly this could have been expanded with some added value to the book. A description is then given of the chemistry of sizes, gums and waxes and their technical applications are outlined.

There follows a series of chapters on the chemical technology of cotton and other cellulosic fibres. In this field, the book is sound and comprehensive and makes an excellent reference work in this field. The thirteenth chapter on linen and man made fibres is a useful contribution but in no way as comprehensive as the work on cotton. A similar comment can be made about the three chapters on wool chemistry and also the seventeenth chapter on the scouring and bleaching of wool. They do, however, give a general survey of the subject and the references are a useful guide to any reader who wishes for a more detailed study of the chemistry of wool and

related products. The final chapter gives a comprehensive survey of the technical chemistry of the mercerization of cotton.

The book is the second of this series, and when the third volume is available the series should make a valuable contribution in the field of the applied chemistry of fibres. F. HAPPEY

OBITUARIES

Dr Jan Kruszynski

DR JAN KRUSZYNSKI, senior lecturer in histology in the University of Liverpool, died on October 14 aged 64.

Kruszynski studied medicine at the Stefan Batory University of Wilno. In his second year, his beautiful histological drawings came to the attention of Professor J. S. Alexandrowicz and soon led to a junior appointment to the teaching staff of the Department of Histology. Kruszynski graduated MD in 1930 and attained the degree of Docent in 1936.

He remained at the Department of Histology at Wilno until his capture by the Russians in 1939. He was a prisoner of war until 1941; he did not care to discuss his terrible experiences during that period. He joined the Polish Army in Russia in 1941, being appointed pathologist to a military hospital, with which he served as it travelled across the Caspian Sea to Italy, via Egypt, Palestine, Iraq and Persia. He reached Britain in 1947. He was appointed assistant lecturer in histology at Liverpool in 1948, lecturer in 1950 and senior lecturer in 1963.

Jan Kruszynski was a gentle, self effacing scholar who gave service of inestimable value to the department and to the medical school as a whole. He had a profound knowledge of classical histology, its literature, its methods and results. His artistic gifts made him a superb illustrator of histological appearances; he went to untold trouble on the students' behalf in preparing demonstrations and lectures illustrated by the clearest of diagrams and drawings. He was always ready to share his wide experience of histological appearances and was consulted by colleagues from many different departments about their problems. His own special research interest was in inorganic histochemistry; from an early stage in his career he was interested in microincineration and became recognized internationally, through lectures and published papers, as the chief authority in that field.

His hobbies reflected his artistic interests: art galleries, photography, engraving and country walking. He will be sorely missed, not only for his professional accomplishments, but for his cheerful, modest personality and the complete integrity of his character. N. M. HANCOX

Dr W. J. Rees

It is a great shock to marine biologists in many countries to learn of Dr W. J. Rees' sudden death on October 12 at the age of 54. He was born on July 2, 1913, and graduated from the University of Wales at Aberystwyth in 1933 and was awarded the DSc in 1942. He is known internationally for his research on three distinct groups of marine animals.

His first research as a postgraduate student at Aberystwyth, was on the helminth parasites of molluscs. He gave this group up somewhat reluctantly in 1936 to become research assistant at the Plymouth Marine Laboratory where he started his researches on the Hydrozoa which were to prove his primary interest for the rest of his life. From 1940 to 1946 he served with the Royal Air Force Volunteer Reserve, first with Coastal Command and later

with the Admiralty where he became a leading authority on the recognition of fishing craft, writing a series of books of reference for the services on fishing craft, first on those of western Europe and then on those of far eastern countries.

In 1946 Rees was appointed to the scientific staff of the British Museum (Natural History) and for the next eight years was in charge of the mollusc section. During this time he published important papers, chiefly on the Cephalopoda, being specially interested in giant squids, and he made very interesting investigations on the larval stages of the octopus in the English Channel. He also did sound work on heteropods and terrestrial gastropods including a report for the Colonial Office on the giant snail, Achatina. He reviewed the breathing devices of terrestrial pulmonates and wrote on the aerial dispersion of Mollusca. He did not, however, conceal his eagerness to return to work on the coelenterates and when the opportunity arose in 1954 he was transferred to the coelenterate section as a principal scientific officer and was able to resume his researches on the Hydromedusae. He did not, however, abandon his interest in the mollusca and was president of the Malacological Society from 1963 to 1966.

Rees pursued his studies in many marine laboratories in Europe and latterly in the United States, and in addition to discovering a number of new species of hydroid was often successful in linking for the first time a known medusa to its hydroid, which was often known by a different name. His interest in the classification of the Hydrozoa culminated in an international symposium on "Cnidaria and their Evolution", which was effectively organized and edited by him for the Zoological Society of London.

J. P. Harding

Dr P. D. F. Murray

DR P. D. F. MURRAY died suddenly on May 17 on board ship while on his way from Australia to Cambridge. He was one of Australia's most distinguished zoologists.

Murray was born on June 18, 1900, at Dorchester. He went to Australia at an early age and was educated at Riverview College and the University of Sydney, from which he graduated with first class honours and the university medal in zoology. He was awarded the Macleay Fellowship of the Linnean Society of New South Wales and began research work for which he was awarded the DSc. After staying for a few years as lecturer, he left Sydney and spent some time at the Universities of Freiburg and Oxford before taking up a Royal Society Smithson Research Fellowship at the Strangeways Laboratory at Cambridge. In 1936 he was appointed university demonstrator at Bedford College and three years later reader in biology and comparative anatomy at the Medical College of St. Bartholomew's Hospital.

In 1949 the Challis chair in zoology in the University of Sydney became vacant and Murray returned to take up this appointment. Ill health, however, forced him to relinquish it and in 1960 he went to the University of New England at Armidale in New South Wales, where he had been appointed reader in zoology. This position enabled him to pursue his research without the heavy load of administration that had undermined his health in Sydney. He retired from this post last year and the university honoured him by appointing him an honorary research fellow.

Besides holding the degrees of the University of Sydney, Murray also held a BSc from the University of Oxford and an honorary MA from Cambridge. When the Australian Academy of Science was established he became one of the Foundation Fellows.

Murray's research interests were in the field of experimental embryology and morphogenesis. While still at the University of Sydney early in his career he carried out work on the development of single somites, of unsegmented mesoderm and of the skeleton in chick embryos.

He used the technique of chorio-allantoic grafts, which, together with tissue cultures, became his major techniques in his later work.

After he left Sydney, Murray continued his research with studies on the development of the heart and the blood vessels and the effects of various cations on the heartbeat and the fibrillation in the developing chick heart. Later he concentrated on experimental studies of the skeletal tissues and during the past few years worked on the histology and the experimental induction of adventitious cartilage.

His research interests, however, do not tell the full story of Murray's role in academic life. He was a man of great modesty but of firm purpose. His clear mind and wide interests in many facets of biology, his integrity and disinterestedness, were generally acknowledged and caused his advice to be sought on many occasions. And because his taking up the position of professor of zoology came at the beginning of a rapid expansion of university teaching with the establishment of new institutions the calls on his advice, his time and his energy were many.

When he took up the readership in the University of New England he was freed from many of the more arduous tasks of administration. He could again concentrate on his research work and the supervision and stimulation of work of younger colleagues. On his retirement he looked forward with keen anticipation to a renewal of old friendships at the Strangeways Laboratory, where he intended to spend the next two years. His sudden death, depriving the world of an outstanding scientist, is therefore the more poignant and tragic.

ALEX STOCK

Professor Carl Kling

PROFESSOR CARL KLING died in July at the age of 88. He became interested in microbiology as a medical student, and after graduation joined the staff of the Swedish National Bacteriological Laboratory. He was appointed director in 1924 and held this post until his retirement in 1945.

In 1911 Sweden experienced what was to develop into one of the most devastating poliomyelitis epidemics ever recorded. Klir g dedicated himself to a study of the epidemiology of the disease and developed an almost obsessive interest in this subject which stayed with him for the rest of his life.

His most significant contribution came in 1929 when, after observations on several European epidemics and a re-evaluation of earlier laboratory findings, he concluded that poliomyelitis must indeed be an intestinal infection. This represented a radical departure from the generally accepted concept of poliovirus as an exclusively neurotropic agent. It took almost ten years and a great deal of confirmatory evidence to convince the medical world that Kling's ideas were essentially correct.

His hypothesis when first presented had rested partly on his intuition and power of scientific imagination. In the following years, in experimental studies of the pathogenesis and epidemiology of the disease, he added much of the substantial evidence that finally revolutionized the concepts of the natural history of poliomyelitis.

In later years he engaged himself in a less fruitless search for extrahuman virus reservoirs. He remained active long after his retirement; only in his last two years did age begin to dampen his spirits.

Under Kling's directorship the National Bacteriological Laboratory g ew to acquire both national and international recognition and long served as Sweden's central breeding place for the microbiological sciences. This development did not take place entirely without controversy. With his refreshingly nonconformist attitude to both life and science, Kling made a few enemies as well as many devoted friends. With him Swedish medical science has lost one of its most colourful personalities.

SVEN GARD

University News:

Bradford

MR D. P. Howson, formerly senior lecturer in the Department of Electronic and Electrical Engineering in the University of Birmingham, has been appointed to the additional chair of electrical engineering, and Dr G. Brown, a reader in physics in the university, has been appointed to a personal chair in nuclear physics. Professor D. C. Johnson, a visiting professor in the university, has been appointed to the chair of industrial technology.

Reading

THE personal title of professor has been conferred on the following: Dr R. N. Curnow, at present reader in applied statistics and head of the Department of Applied Statistics; Dr G. W. Maynard, at present reader in economics; Mr E. J. Rolfe, principal of the National College of Food Technology; Dr B. G. F. Weitz, director of the National Institute for Research in Dairying.

Salford

DR G. O. PHILLIPS, formerly senior lecturer in chemistry at the University College of South Wales, has been appointed professor of chemistry.

Appointments

MR A. E. BAILEY, formerly head of the Strategic Systems Division at the Signals Research and Development Establishment, has been appointed superintendent of a new Division of Electrical Science at the National Physical Laboratory.

MR F. H. Felberg has been appointed assistant laboratory director for plans and programmes in the Jet Propulsion Laboratory, California Institute of Technology; Mr J. N. James has been appointed to Mr Felberg's former position of assistant laboratory director for Technical Divisions.

Announcements

MR F. L. WARING, deputy chairman and managing director of Coalite and Chemical Products Ltd, has been elected president of Chemical Industries Association, in succession to Sir Peter Allen, deputy chairman of Imperial Chemical Industries Ltd.

AT the annual statutory meeting of the Royal Society of Edinburgh on October 23, 1967, the following were elected officers and council for the session 1967-68: President, Professor N. Feather of the University of Edinburgh; Vice-presidents, Professor C. H. Waddington of the Institute of Animal Genetics, Edinburgh; Dr H. E. Butler of the Royal Observatory, Edinburgh; Professor I. N. Sneddon of the University of Edinburgh; Dr J. R. Peddie of Edinburgh; Professor T. C. Phemister of the University of Aberdeen; Professor J. D. Robertson of the University of Glasgow; General Secretary, Professor A. E. Ritchie of the University of St. Andrews; Secretaries to Ordinary Meetings, Sir William Weipers of the University of Glasgow Veterinary Hospital; Professor Neil Campbell of the University of Edinburgh; Treasurer, Lord Balerno of Currie; Curator, Dr R. Schlapp of the University of Edinburgh; Ordinary Members of Council, Professor P. W. Brian of the University of Glasgow; Sir David Lowe; Dr D. G. Sopwith; Professor E. M. Patterson of the University of Aberdeen; Professor P. D. Ritchie of the University of Strathclyde; Professor R. S. Silver of the University of Glasgow; Professor H. W. Wilson of the Scottish Universities' Reactor Centre; Professor W. N. Everitt of the University of Dundee; Professor N. Kemmer of the University of Edinburgh; Dr D. Traill of Edinburgh; Professor G. R. Tristram of the University of St. Andrews; and Dr C. D. Waterson of the Royal Scottish Museum, Edinburgh.

Meetings

PERMEABILITY Problems, July 2-9, 1968, Jerusalem (The Secretariat, Symposium on Permeability Problems, Polymer Department, Weizmann Institute of Science, Rehovoth, Israel).

CORRIGENDUM. In the article "Theoretical Astronomy at Cambridge", by F. L. Westwater (*Nature*, 216, 432; 1967) the SRC grant was incorrectly given as £25,000. This should have been £250,000.

CORRIGENDUM. In the article "Bacterial Inhibitors in Milk and other Biological Fluids" by B. Reiter and J. D. Oram (Nature, 216, 328; 1967) the last sentence should read "... and less than 1 µg of purified lipopolysaccharide (E. coli 005: B5, Difco) produces leucocytosis in 4-5 h".

ERRATUM. In the obituary of Sir John Cockcroft (*Nature*, 216, 621; 1967), m.amp should read μamp. The site for the heavy water reactor on the Ottawa River was selected in 1945, not 1946.

ERRATUM. In the article "Formation of Zinc Ferrite at Low Temperatures" by J. Beretka and M. J. Ridge (Nature, 216, 473; 1967), in the second line of the fourth paragraph organic oxides should read R₂O₂, and in the ninth line of the fourth paragraph the word chlorine should read chloride.

CORRESPONDENCE

Assessing the AGR

Sir,—To put your recent article on "Assessing the AGR" (Nature, 216, 213; 1967) in its proper perspective, we ought to emphasize a few points and add some comments to what was written.

Although the AGR came out unfavourably compared with the other systems in our assessment, the differences in terms of generating costs are marginal. Taking into account the uncertainties in the basic cost data used, we would agree with AEA that our results are by no means conclusive and we would further agree that only through actual tendering will it be possible to establish the real costs.

The fact that we for a certain period concentrated on a more extensive comparison between light and heavy water boiling reactors should not be given more importance than we in Norway have attached to it—a mere continuation of our paper exercise.

The cost picture for the different reactor types is changing rapidly and, as AEA points out, there has, since our assessment was carried out, been a general increase in the cost of light water reactors while there has been a definite decrease in the cost for the advanced gas cooled reactor. It is also generally acknowledged that the AGR has more to gain from a further development than have the light water reactors.

Since the results referred to in your article were published, we have obtained additional cost figures for both the AGR and the American light water reactors (PWR and BWR) indicating that, according to our ground rules, the generating costs for these reactors now work out roughly equal.

With due regard to the above development, we decided earlier this year to include an AGR in our reference design study of a 500 MWe nuclear power plant under Norwegian conditions. We have recently initiated a collaboration with UKAEA Reactor Group, Risley, to carry this study through.

Yours faithfully,

HENRIK AGER-HANSSEN Assistant Director, Project Manager.

Institutt for Atomenergi. Kjeller.

FORTHCOMING EVENTS

1986

(Meetings marked with an asterisk are open to the public.)

Monday, November 20

BRITISH SOCIETY FOR THE HISTORY OF SCIENCE (at the Science Museum, Exhibition Road, London, SW7), at 5.30 p.m.—Mr F. I. G. Rawlins: "Physical Chemistry or Chemical Physics—a History of Two Movements".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 5.30 p.m.—Dr W. D. Humpage and Dr T. N. Saha: "Digital Computer Methods in Dynamic Response Analysis Turbogenerator Units".

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, WC1), at 5.30 p.m.—Dr Arthur Engel: "Perspectives in Health Planning. III. Mass Screening for Asymptomatic Disease as a Public Health Measure". (Third of four Heath Clark Lectures.)*

Society for Analytical Chemistry, Radiochemical Methods Group (at the Pharmaceutical Society, 17 Bloomsbury Square, London, WCI). at 6 p.m.—Annual General Meeting, followed by Dr P. G. Jeffrey: "The Application of Isotope Neutron Sources in Analytical Chemistry"; Dr K. Ansell: "Isotope Radiation Sources for X-ray Analysis"; Mr J. Johnston: "Bremsstrahlung Methods in Industry".

Tuesday, November 21

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College London, Gower Street, London, WC1), at 1.20 p.m.—Mr A. N. Maxwell: "How are Sensations Related to Brain Processes?".*

UNIVERSITY OF LONDON (in the Chemistry Department, Imperial College of Science and Technology, London, SW7), at 5 p.m.—Professor J. H. de Boey (Technological University of Delit): "Solved and Unsolved Problems after 40 Years of Adsorption Research".*

SOCIETY OF INSTRUMENT TECHNOLOGY (joint meeting with the Plastics Institute, at the Institution of Electrical Engineers, Savoy Place, London, WC2), at 5,30 p.m.—Mr D. Grant and Mr P. Wilkinson: "Temperature Control Extrusion"; "The Requirements for Temperature Control D. E. A. Brooks and Mr P. R. Lever; "Strategies for the Temperature Control of Extruders".

University of Aston in Birmingham (at Gosta Green, Birmingham, 4), at 5.30 p.m.—Professor E. Braun: "Commonsense and Physical Law" (Inangural Lecture).

UNIVERSITY OF LONDON (at the Institute of Child Health, Guilford Street, London, WC1), at 5.30 p.m.—Dr F. H. Doyle: "Radiological Measurements in Endocrine and Metabolic Diseases". (Eleventh of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)*

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, WC1), at 5.30 p.m.—Dr Arthur Engel: "Perspectives in Health Planning. IV. The Swedish Regionalized Hospital and Health System". (Last of four Heath Clark Lectures.)*

UNIVERSITY OF LOXDON (in the Botany Theatre, University College London, Gower Street, London, WC1), at 5.30 p.m.—Dr D. H. Notthcote: "Growth and Differentiation of Plant Cells" (further lecture on November 22).*

UNIVERSITY OF SURREY (in the Great Hall of the University, Battersea Park Road, London, SW11), at 5.30 p.m.—Professor J. Waterlow: "The Body's Need for Protein—a Challenge for Research".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), ten Design" opened by Mr N. L. Sigournay, and a speaker from the Decca Navigator Co.

INSTITUTION OF MECHANICAL ENGINEERS, APPLIED MECHANICS GROUP (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p.m.—Discussion Meeting on "Art, Science and Technology in Engineering Design".

Society of Chemical Industry, London Section (at 14 Belgrave Square, London, SW1), at 6 p.m.—Mr G. W. Hemy: "The Russian Chemical Industry".

INSTITUTION OF THE RUBBER INDUSTRY, LONDON SECTION (at the Eccleston Hotel, Victoria, London, SW1), at 7 p.m.—Mr. H. G. Parker: "Health Hazards in the Rubber Industry".

SOCIETY FOR ANALYTICAL CHEMISTRY, SPECIAL TECHNIQUES GROUP (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W1), at 7 p.m.—Twenty-third Annual General Meeting, followed by Dr G. F. Reynolds: "Advances in Electrophoresis".

Tuesday, November 21-Thursday, November 23

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2)—Conference on "Servocomponents".

Wednesday, November 22

Geological Society (at Burlington House, Piccadilly, London, W1), at 5 p.m.—Dr George W. White: "Pleistocene Deposits of the North-West Allegheny Plateau"; Dr A. C. Dunham: "The Felsites, Granophyre, Explosion Breccias and Tuffisites of the North-Eastern Margin of the Tertiary Igneous Complex of Rhum, Inverness-shire".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 5.30 p.m.—Dr J. Evans: "Solid State Electronics".

INSTITUTION OF MECHANICAL ENGINEERS (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p.m.,—Mr I. I. Artobolewskii: "Some Aspects of the Development of the Theory of Automatic Machines by Soviet Scientists".

UNIVERSITY OF LONDON (at the Institute of Neurology, National Hospital, Queen Square, London, WCI). at 6 p.m.—Dr A. M. Jelliffe and Dr P. T. Lascelles: "The Use and Misuse of Ionizing Radiation in Neurology—Clinical and Biochemical Aspects".*

SOCIETY OF CHEMICAL INDUSTRY, FOOD GROUP (joint meeting with the Plastics and Polymer Group, at 14 Belgrave Square, London, SW1), at 6.15 p.m.—Dr W. A. P. Black: "The Use of Aigal Polysaccharides in the Food Industry".

Thursday, November 23

ROYAL INSTITUTION (at 21 Albemarle Street, London, W1), at 2.30 p.ms.—Professor George Porter, F.R.S.: "Thermodynamics and Chemical Change" (Civil Service Lecture).

UNIVERSITY OF LONDON (at the Middlesex Hospital Medical School, Cleveland Street, London, W1), at 5 p.m.—Professor A. Kekwick: "Food and Energy".*

University of London (at the Institute of Child Health, Guilford Street, London, WC1), at 5.30 p.m.—Dr H. K. Weinbren: "Control of Growth and Regeneration in the Liver". (Twelfth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)*

INSTITUTION OF MECHANICAL ENGINEERS, EDUCATION AND TRAINING GROUP (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p.m.—Discussion Meeting on "The Place of Liberal Studies in Engineering Courses".

INSTITUTION OF ELECTRICAL ENGINEERS, LONDON GRADUATE AND STUDENT SECTION (at Savoy Place, London, WC2), at 6.30 p.m.—Professor J. G. Davies: "Radio Astronomy".

Friday, November 24

ROYAL INSTITUTION, PHOTOCHEMISTRY DISCUSSION GROUP (at 21 Albemarle Street, London, W1), at 1 p.m.—Dr J. R. Froines: "Studies of Chlorophyll Monolayers".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 2.30 p.m.—Colloquium on "Integrated Circuits and Logical Design with Integrated Circuits. (b) Partitioning with Integrated Circuits".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 5.30 p.m.—Lt.-Col. R. H. Smith, R.E.M.E. (retd.), T.D.: "Developments Since 1897 of Technical Equipment Used by the London Electrical Engineers".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W1), at 9 p.m.—Professor Pearce Williams: "Michael Faraday and the Ether—a Study in Heresy".

Friday, November 24-Sunday, November 26

INSTITUTION OF MECHANICAL ENGINEERS, THE OPERATIONAL RESPASSOR SOCIETY, and the BRITISH COMPETER SOCIETY (at The Grand Hotel, Eastbourne)—Joint Conference on "Problems of Project Management Using Network Analysis".

Saturday, November 25

BOTANICAL SOCIETY OF THE BRITISH ISLES (in the Botany Department, British Museum (Natural History), Cromwell Road, London, SW7), from 2 p.m. to 5.30 p.m.—Annual Exhibition Meeting.

INNER LONDON EDUCATION AUTHORITY (at the Horniman Museum, London Road, Forest Hill, London, SE23), at 3.30 p.m.—Dr J. M. Cullen: "Colour and the Eye—Experiments on the Role of Colour in Animal Behaviour".*

Monday, November 27

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2)-Colloquium on "Energy from Natural Gas".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W1), at 1.15 p.m.—Professor L. Pearce Williams: "Physics and Philosophy in the Early Nineteenth Century".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 5.30 p.m.—Dr C. S. E. Phillips: "Computers and Adaptive Radar".

INSTITUTION OF ELECTRICAL ENGINEERS (joint meeting with the Automatic Control Group of the Institution of Mechanical Engineers, at 1 Birdage Walk, Westminster, London, SW1), at 6 p.m.—Discussion Meeting on "Systematic Approach to Design", opened by Mr R. L. Latham and Mr G. J. Terry.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the

dates mentioned:
TEMPORARY ASSISTANT LECTURER IN PHILOSOPHY—The Registrar, The University, Sheffield (November 27).
TEMPORARY LECTURER/SENIOR LECTURER IN MATHEMATICS AT Britannia Royal Naval College, Dartmouth, Devon—Ministry of Defence, Navy Department SEI(N) 368, Old War Office Building, London, SWI (November 672)

CHAIR OF PHYSIOLOGY at St. Mary's Hospital Medical School—The Academic Registrar, University of London, Senate House, London, WC1 (December 1).

(December 1).

DEMONSTRATOR (male or female, medically qualified) in the DEPARTMENT
OF ANATOMY—The Registrar and Secretary, The University, Bristol
(December 4).

LECTURERS (2) IN CIVIL ENGINEERING at the University of Queensland,
Australia—The Association of Commonwealth Universities (Branch Office),
Marlborough House, Pall Mall. London, SW1 (London and Brisbane, December 2).

Mariborough House, Pail Mall, London, SWI (London and Brisdare, December 8).

Research Associate/Senior Research Associate (graduate with experience of electronic circuits and preferably some knowledge of acoustics) in the Department of Electronic and December 18, to work on a challenging project concerned with the exploitation of non-linear acoustice phenomena in a new type of sonar system—The Assistant Registrar (8). P.O. Box 363, The University, Birmingham, 15 (December 9).

PROFESSOR OF MATHEMATICS at the University of Ife. Nigeria—The Inter-University Council, 33 Bedford Place, London, WC1 (December 12).

LECTUERR OF ASSISTANT LECTURER in the DEPARTMENT OF MATHEMATICS—The Secretary, University of Edinburgh, Old College, South Bridge, Edinburgh (December 15).

READER OF SENIOR LECTURER IN PHYSICAL CHEMISTRY; and a SECON LECTURER of LECTURER (preferably with interests in organometable chemistry) in Organic Chemistry—The Registrar, The New University of Ulster, Coleraine, Northern Ireland (December 15).

LECTURERS/ASSISTANT LECTURERS (with at least a good honours degree or equivalent, plus suitable teaching and research experience, and preferably specialized in one of the following fields: inorganic chemistry, analytical chemistry, physical chemistry or chemical technology) in Chemistry at the University of Malaya—The Association or Commonwealth Universities (Branch Office), Mariborough House, Pall Mall, London, SW1 (Kuala Lumpur and London, December 17).

SENIOR LECTURER, LECTURER or ASSISTANT LECTURER IN SCIENCE EDUCATION, with special reference to the teaching of mathematics at the University of Zambia—The Inter-University Council, 33 Bedford Place, London, WC1 (December 17).

TION, with special reference to the teaching of mathematics at the University of Zambia—The Inter-University Council, 33 Bedford Place, London, WC1 (December 17).

LECTURER/SENIOR LECTURER (preferably with interests in one or more of the following fields: economic geography, urban geography, biogeography, South-East Asia) in the DEPARTYENT OF GEOGRAPHY. Monash University—The Academic Registrar, Monash University, Clayton, Victoria, Australia; or The Secretary-General, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (December 22).

LECTURER IN ENTRACTIVE METALLURGY at the University of Queensland, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (London and Brisbane, December 31).

PROFESSOR OF APPLIED PSYCHOLOGY at the University of New South Wales—The Secretary-General, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (Australia and London, December 31).

SENIOR LECTURER OF LECTURER IN PSYCHOLOGY at Flinders University of South Australia—The Secretary-General, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (Australia and London, December 31).

SENIOR LECTURER OF LECTURER IN PSYCHOLOGY at Flinders University of South Australia. Bedford Park, South Australia (December 31).

CHAIR OF ELECTRONICS at Chelsea College of Science and Technology—The Academic Registrar (A), University of London, Senate House, London, WC1 (January 3).

CHAIR OF ENTROPOLOGY at the London School of Economics—The Academic Registrar (A), University of London, Senate House, London, WC1 (March 1).

(March 1).

HEADSHIP OF THE DEPARTMENT AND CHAIR OF PHYSICS—The Academic Registrar, The City University, St. John Street, London, EC1, quoting ref. P/T.

LECTURER IN ANTHROPOLOGY; and a LECTURER IN SOCIOLOGY at the University of Queensland, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1.

SENIOR LECTURER (man or woman with good academic qualifications) in MATHEMATICS; and a LECTURER (man or woman with good academic qualifications) in MATHEMATICS—The Secretary to the Principal, Homerton College, Cambridge.

HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue.

The direct postal price per subscription for one or two copies of NATURE each week is:

*12 MONTHS (52 issues and 4 indexes)

Great Britain and Eire.....

(Charge for delivery by air mail on application)
*Shorter periods pro rata. (Minimum three months.)

MULTIPLE SUBSCRIPTIONS

For subscribers who take more than two copies of NATURE each week these reduced annual rates are offered:

12 MONTHS (52 issues and 4 indexes)

Number of	G.B. &	U.S.A. Canada		Elsewhere
Copies	Eire	(by air freight)		(surface mail)
3–5 6–11 12 or more	Each £13.10.0 £12.15.0 £12.0.0	Each \$46.50 \$44.50 \$42.50	Each \$50.50 \$48.30 \$46.00	Each £13.10.0 £12.15.0 £12.0.0

Multiple subscriptions must run concurrently. Every copy will be posted separately, and for speed of delivery each subscription can be addressed to a different individual, or department at the same address. (ZIP essential for U.S.A.)

Mr Wedgwood Benn's Epistle to Caithness

MR WEDGWOOD BENN obviously fancies himself as a letter writer but, on the evidence of his letter to the fast reactor men at Dounreay, he has some way to go before he ranks with St Paul and Jonathan Swift or even Sir Harold Nicolson. To be sure, when he warned the people at Dounreay against the blandishments of the Westinghouse Company, he did not know for certain that there was devaluation just around the corner. That might have made him choose more subtle phrases or even silence. In the event, however, no great harm seems to have been done. Those already talking to the company have not been maddened by the unction of Mr Wedgwood Benn's declaration to clinch the deal. Those already determined to stay because they like their work or their life have seemed not to have been persuaded to reconsider their decisions now that they have been told that they should stay in Britain out of a sense of guilt, not necessarily from a sense of purpose. Everybody will be glad of

At the same time, it would be a great misfortune if the content of Mr Wedgwood Benn's letter were to be forgotten simply because it has done as little harm as good, particularly in a week when the international value of the British currency has had to be reduced. The sad truth is that Mr Wedgwood Benn has fallen into a great many of the pitfalls in the relationship between corporate employers and technical employees which the Jones Committee on the brain drain was complaining about only a few weeks ago.

The problem which must now be faced quite squarely by employers of technical manpower in Britain and other countries similarly placed is that for all practical purposes there is now an international market in technically skilled manpower. This, in a nutshell, is the message of the Jones Report. This is the reason why that committee spent so much of its time urging that industrial employers should now be cajoled into paying better salaries to scientists and engineers. This is why it asked that means should be found of promoting more scientists and engineers to positions of responsibility. And what applies to industrial employers should also apply to the British Government. In short, even if Mr Wedgwood Benn is right in his assertion that Westinghouse is making a deliberate attempt to tempt away skilled people with special knowledge of the fast reactor now being designed in Britain, it cuts very little ice for him to say in reply that "no Westinghouse establishment has got the facilities, scope or resources that Britain has made available to you through the Atomic Energy Auth-

ority". A part of the trouble is that continuing uncertainty about the future of the Atomic Energy Authority does not fully reassure those who fear that the splendid work so far accomplished as part of the fast reactor programme will be fully and energetically exploited. But it is also entirely proper that scientists and engineers should be concerned with the kind of life which they and their families are able to enjoy. There is—or there should be—no shame in making cold-blooded calculations that life could be more attractive elsewhere.

But how to strike a balance between emigration and staying at home? Skilled people throughout Europe are continually having to make this kind of calculation. This is not merely a recurring necessity but an important intellectual exercise in its own right, and it deserves to be brought more explicitly into the open. In particular, it is wrong to hide from the plain fact that the economic standard of life, and quite often its quality, is demonstrably better in North America than anywhere in Europe. And who is to say that a British scientist or engineer behaves scandalously by going off to the United States to work if he does so because of a cold-blooded calculation that his children would then have a better chance of going to a university? Who can complain if somebody chooses to leave for the United States because he and his family, for any one of a host of reasons, will then be happier? Everybody has his own calculation to make. On the face of things, at least, the benefits of crossing the Atlantic towards the west are bound to be immense for a great many European families. The wonder is not that there is such a flood of emigrants, but that so many people stay behind in places like Dounreay.

This is the point at which the sharpest rejoinder to Mr Wedgwood Benn's epistle suggests itself. true, of course, that special groups of people such as the designers of the fast reactor now being built in Scotland are likely to be particularly valuable to the Atomic Energy Authority in the years ahead. So why not pay them more? Money may not be everything, but it is important—even in remote places such as Dounreay. And although salaries in the Atomic Energy Authority compare favourably with those in the Government service proper, and even with those in industry, they are by no means the kinds of salaries which give those who receive them a sense of being well paid. Much younger men with a flair for knowing about computers can often earn much more, for example. But, worse still, there is a great rigidity about the pattern of salaries in the public corporations.

The hierarchical pattern cannot be too much distorted without causing trouble. And for all the technical excitement of the work they do, the people at Dounreay must be well aware that there is very little prospect of the kind of salary which, in Britain, is to be counted as more than merely modest. So much can be told from the way in which Sir Richard Clarke was boasting modestly, earlier this week, of the way in which the Ministry of Technology now employs more than seventy people at salaries of more than £5,000 a year. The trouble, of course, is that a good many quite small companies could probably make a prouder boast. And if somebody from Dounreay decides to try his luck in industry, is there any reason to expect that he will first bestow his favours on some British company? The Jones Committee made several useful suggestions for improving the attractiveness of British industry, but nothing much has been done about them yet.

It is more difficult to make a list of the reasons why people stay in Europe, although this is just as important. But it would be wrong to think that mere inertia has led the continued presence of people with saleable skills in Western Europe—even as far north For one thing, Europe remains an as Caithness. interesting place in which to live. People are varied and enterprising. The place is intellectually alive. The rewards are not always cancelled out by the frustra-Yet there is one quality of life in Western Europe and particularly in Britain which is increasingly a thorn in the flesh of those who have not yet emigrated. In one way and another, the pattern of life has become too rigid and inflexible. People may be fully agreed on some course of action but apparently powerless to follow it through.

The events of the past few months in Britain contain many splendid illustrations of this sad truth. Every-

body has agreed, for twenty years, that there will have to be some kind of national reference library for science and technology, but it will be the best part of a decade yet before the real need is met. The educational system is ripe for change, particularly at the interface between the schools and the universities yet nothing much is happening (but see page 740). The Economic Planning Council for the South-East of England has produced a plan the most obvious virtue. of which is that nobody is likely to take it seriously. Closer to Mr Wedgwood Benn's parish, the Atomic Energy Authority remains uncertain of its future after what amounts to between two and four years of continuous uncertainty. Occasionally it seems as if any change, more or less in any direction, would be better than the accidie, which seems from time to time to infest some parts of Western Europe.

There is no doubting Mr Wedgwood Benn's views and his ministry's objectives on this general issue. Almost by definition, they are on the side of change. Yet there remains a curious air of stillness. Things stay much the same, and those who are most hamstrung by circumstances are also prevented by circumstances from battling on their own behalf. The fast reactor men are good examples. In this sense the paternalism of Mr Wedgwood Benn's assurance that he will regard fast reactors as his favourite children from now on will be less valuable than would have been some greater sense that the men involved in the development of fast reactors could also have felt more able to influence the uses that will be made of these machines in the years ahead. This is the direction in which Mr Wedgwood Benn should push. It is also a point which he should keep in mind when reading the report of the Select Committee of the House of Commons on the nuclear power industry.

Relations between Universities and Schools

THE meeting of the academic advisory committee called by the Committee of Vice-Chancellors (see page 740) has been a great success, but it would be wrong to think that there are now no problems left in regulating the transition between schools and universities. For several months there have been signs that the universities have been coming round to the belief that a more liberal curriculum in the sixth forms would be a great advantage. A host of university lecturers in economics, now forced to spend time teaching mathematics to undergraduates, are among the most recent recruits to this point of view. Yet there cannot at this stage be any certainty that the enthusiasm for change among the delegates to the vice-chancellors' meeting will be fully echoed in the universities.

Even if there should be general agreement that reform has somehow become essential, the universities are likely to be hard pressed in putting forward some constructive alternative to the proposals of the Schools Council. Should there be four subjects or five in the school-leaving curriculum? How great should be the element of compulsion? It would be a splendid

thing if the universities and schools could agree that mathematics should be an essential part of every university entrant's studies, but this is asking a great deal. Another complex of problems yet to be tackled is the extent to which the universities will accept one of the most radical implications of the course upon which they have embarked—the likelihood that many students arriving at universities will have had no specific preparation in the particular specialisms of of which they wish to make a special study. This will be a sharp break with the British tradition, but it has also become a necessity. In the circumstances, nobody will be surprised if many universities decide that most undergraduate courses will have to last four years and not three.

There are also formidable problems to be tackled in the relationship between the universities and the schools. In the past few years, the pressure of the competition for places at the universities has persuaded many schools that the most urgent need is somehow to reduce the burden of external examinations. This is the origin of the Schools Council's plan for a sixth

form curriculum in which students seeking entrance to a university would follow only two externally examined courses. The university representatives at the vicechancellors' meeting were right to argue that these proposals would narrow and not broaden the education of students reaching the universities, but this seems not to be the present interest of the schools. Obviously it will be hard for the universities now to push them in the direction of extra examinations. The fact that *the examinations may be less exacting will not entirely comfort those schools in which teachers value jealously their right to mimic the universities in the sixth forms. Evidently the universities will need not merely a reasonable and coherent case to put to the Schools Council in the spring, but tact as well. If they are wise, they will pay close attention to Professor Butler's argument for deliberate experiment, and there is, of course, no reason why the universities should not elect, without further discussion, to embark on some of the controlled experiments which the introduction of a more liberal curriculum in the schools will make essential. But if this is to be the method, the universities will have to hurry. Britain has waited too long already for a more sensible pattern of education in the schools. If there are to be experiments, there is no reason why they should not begin in September 1968.

Hung Jury

ALTHOUGH it is too soon properly to assess the first report of the Select Committee on Science and Technology appointed by the House of Commons, one thing is already clear—the committee has done its reputation a great disservice by coming out with a report which is crudely divided on party grounds. The committee's credibility has already suffered from its lack of the professional assistance that would have enabled it to ask more penetrating questions. Its failure to agree on proposals for the reorganization of the civil nuclear power industry is a greater setback. The committee might have done better to contain its ambitions within its capabilities, on this first exercise at least.

"In present circumstances, the best interests of the country would be served by the combination in a single organization or company of the skill and resources of those now separately engaged in the design and construction of nuclear boilers." With this sentence the Select Committee on Science and Technology finally resolved discussion of its examination of the nuclear power industry in Britain. The report of the committee, published on November 22, comes down. by a majority of 7 to 5, in favour of what has become known as a "central design authority". sortium system, it says, should be phased out, and the generating boards should be free to place contracts with individual companies for nuclear stations in the same way as they do for conventional stations. The commercial research and development of the AEA should go to the single nuclear boiler organization or company. The AEA should, however, retain its responsibility for pure research, and the Government should carry out a full review to make sure that it is concentrating on pure research, and that any functions not "inextricably linked" to the primary task are

passed to more appropriate organizations. This clearly is a reference to the diversification into fields such as desalination which the AEA has been engaged on.

In the production of fuel, the AEA monopoly should be broken by the establishment of a new British fuel supply and manufacturing company, which should include the AEA and others-Rolls-Royce is one possibility. In the export market, the British Nuclear Export Executive should be wound up, but the committee proposes no new organization to take its place. Instead, there should be a survey by the Board of Trade of export markets-hardly an inspiring rallying cry. The committee seems enthusiastic about high temperature reactors—partly on the evidence of the sub-committee which visited Europe—and says that high temperature reactor research should be supported. and that the Dragon reactor should be kept going, if necessary by Britain alone. Water reactors, the committee says, and particularly the steam generating heavy water reactor, should be speeded up. Finally, marine nuclear power is given support, if only in the recommendation that a departmental committee should be set up to examine the possibilities. As for fusion, the committee says that the Ministry of Technology should review the whole field of fusion research to ensure that Britain takes advantage of any technological breakthrough.

The committee seems keen to chip away at the power of the AEA. The AEA holds, it says, "a position of considerable advantage". In another place, it is described as "virtually unassailable". To counteract this, a technical assessment unit should be set up to advise the Government on the merits of AEA projects. The committee would also like to see the emergence in Britain of a body like the United States Joint Congressional Committee, with an expert staff.

The questions which the report leaves unanswered give plenty of room for further argument. If the AEA is to be divided, where will the division fall? Will the change in responsibility of the AEA need parliamentary legislation? And the greatest ambiguity of all—will the central design authority be an organization like the AEA is now, or will it be more like a nationalized industry? Throughout the report, it is referred to as a "single organization or company", no doubt in part to give way to Conservative critics. The saddest thing about the report is that it is not unanimous; the division along party lines may well have the effect of reducing the argument to party terms.

Counting Heads

In Britain, more graduates are going on to further study or training than are entering industry. situation, first documented by the Swann Committee report, has been substantiated by a report just issued by the University Grants Committee. But there has been a narrowing of the gap between the two careers —the number going on the postgraduate training or research rose from 12,084 in 1964-65 to 13,417 in 1965-66, while the number going into industry went up from 10,904 to 12,851. If the trend continues, industry will this year be taking almost exactly as many graduates from British universities as choose to remain in academic life or teaching. The balance, almost 20 per cent, includes overseas students going home. British students going abroad, married women and the unemployed. Happily, the last category is comparatively small; at the end of December 1966, 3 per cent of arts and social science graduates were still looking for work, while only 1-6 per cent of scientists were still looking. While the trend is an encouraging one, not too much should be made of it, as for the first time the colleges of advanced technology have been included in the list—and they send 67 per cent of their graduates into industry.

The report shows that the total number of graduates in 1965-66 was 32,166, while 5,821 qualified for higher The statistics show how many of these graduates went overseas, either permanently or temporarily. Among first degree graduates, only a small and relatively constant proportion admitted to joining the brain drain; in pure science, for example, 1.2 per cent of men went overseas for further training or research while 1.3 per cent took permanent employment overseas and 1.5 per cent temporary employment overseas. The figures are higher for applied science— 3.4 per cent of men graduating in applied science gained permanent employment overseas. Among higher degree graduates, the proportions are much higher; 7 per cent took up permanent employment overseas, and 6 per cent took up temporary employment. The figures for higher graduates in pure science show an interesting trend; in 1965, 13.9 per cent took up permanent employment overseas, while only 4.7 per cent took short-term employment. By 1966, however, possibly as a result of the adverse publicity of the brain drain, only 6.8 per cent admitted to taking permanent employment overseas, while the number who said that their overseas employment was short term had shot up to 11.8 per cent. The total, 18.6 per cent, is exactly the same in each year, so it looks as if employers abroad, or graduates going abroad, are responding to criticism of the brain drain by claiming that the appointments are short term. Applied scientists have no such scruples—only 1.8 per cent said that their jobs overseas were short term, while 8.5 per cent said that they were permanent.

Strings with the Money

The University Grants Committee has now sent to Vice-Chancellors a memorandum which sets out the pattern for universities over the next five years. The financial allocation was made public several weeks ago, and the UGC has now followed this up with some indication of its philosophy. The memorandum does not attempt to establish hard and fast rules for university development, but tries to put the financial provisions into context. "... It did seem at this point of time there would be certain background factors or general lines of development to which it would be proper for the committee to call attention."

The most startling recommendation in the memorandum is made in an almost throwaway style. After saying that undergraduate numbers are "a genuine priority" because of pressure from the schools, the report says that "the major increase must be in the number of arts-based, rather than science-based, students". This recommendation is made in the light of A-level trends, which show the now familiar swing away from science. As for postgraduates, the UGC says that the expansion it has allowed for is in many cases smaller than the universities wished, and gives a

number of reasons for this; as well as the pressure on undergraduate places, there is the fact that the proportion of undergraduates going on to higher degrees already exceeds the Robbins estimate, and that too many are staying in the universities. Finally, the slowing of the expansion in the universities means that the demand for recruits to university staffs will slacken off.

There is also talk in the memorandum of the unit costs of universities. In a passage which will no doubt alarm some Vice-Chancellors, the UGC says that the unit costs of universities are one of the considerations which should be taken into account in the distribution of grants. The UGC, the memorandum says, has a considerable amount of information on the subject, and it has "made some adjustments where there seemed to them to be under—or over—financing of individual universities in relation to their responsibilities".

The memorandum also makes encouraging noises about collaboration between universities and between universities and industry. Collaboration with institutions in the "non-autonomous" sector should also be encouraged, and the committee welcomes the investigations into the use of plant and equipment which the Committee of Vice-Chancellors and Principals has set in motion. In letters to universities, the UGC has indicated certain areas which it believes merit greater support, and for which more money has been supplied (though not on an earmarked basis). These include libraries, for which expenditure should increase by 20 per cent, administration, audio-visual aids, computer maintenance, and other developments such as dentistry, management studies and town and country planning.

Other areas, on the other hand, get a cooler appraisal. The committee has recommended that agriculture departments at three universities should close, and that some concentration of resources in agricultural economics is also desirable. Although there should be more student architects, there should not be more schools of architecture; equally, there should be no more schools of biological sciences, although the committee has not yet recommended that any be closed down. Social studies should see a big expansion, but mainly at universities already entrenched in the subject. Particular importance is attached to the development of economics, law and statistics.

New Director-General

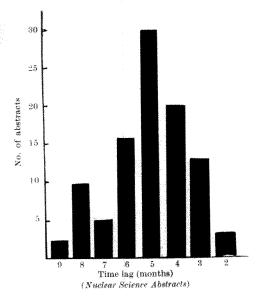

On November 20, Dr A. H. Boerma was elected Director-General of the United Nations Food and Agriculture Organization. He succeeds Dr B. R. Sen of India. Of Dutch origin, Dr Boerma is no stranger to FAO: for the past five years he has been Executive-Director of the World Food Programme. Before that he represented the Netherlands on the FAO council before becoming the organization's regional representative for Europe from 1948 to 1951. Dr Boerma has not so far committed himself publicly to a policy for FAO in the years ahead, but the annual conference now being held in Rome will be an opportunity for him to take soundings among the member governments. It will be interesting to see whether a man from the developed world will be entirely acceptable to underdeveloped countries. At the FAO as elsewhere, however, change at the top can be enlivening by itself.

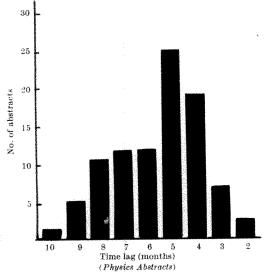

Slow Abstracts

How useful are abstracts? Because of the expansion of scientific literature, many of the functions once performed by scientific journals are now taken over by the abstract journals. By scanning more primary publications than any individual is able to, the abstracts provide a running record of what has been published

and keep their readers up to date.

But examination of two abstract journals in physics Physics Abstracts, published by the Institution of Electrical Engineers, and Nuclear Science Abstracts, published by the United States Atomic Energy Commission—shows that their readers are by no means as up to date as they might be. The distribution curves show the time lags calculated for October editions of both abstract journals. The delay times are those between the publication of the original paper and the appearance of an abstract of it. The curves were calculated from the dates of original publication given in the abstracts. The figures thus take no account of the abstracts for which no date is given. The figures are based on two counts, each of 100 abstracts, taken at random from corresponding editions of Physics Abstracts and Nuclear Science Abstracts. The curves

show that Nuclear Science Abstracts is slightly the quicker of the two-the median date of publication for abstracts listed in the issue of October 15 was June 4, 1967. For Physics Abstracts, published nominally on October 1, the median date of original publication was May 18, 1967. Physicists thus had to wait nearly five months in order for abstracts to appear. In some cases, of course—and particularly in Nuclear Science Abstracts-they had to wait even longer; a cursory reading of the journal brought to light a British patent-"Improved Process for the Production of Graphite" granted as long ago as January 11, 1961, and with a priority date in France of February 29, 1956. Unfortunately, it is not only patents which take a long time to seep through; the same issue of Nuclear Science Abstracts contains a Russian paper published in English translation in January 1961, and an article from New Scientist ("Medical and Surgical Uses for the Laser", by Leon Goldman) which appeared in January 1964. Really out of date papers are much less common in Physics Abstracts, possibly because it does not include patents.

The IEE is conscious of the delay, and is hoping to accelerate the process and reduce the backlog. The recent move of the publications department to Stevenage has caused transitory difficulties, but should ultimately help to speed the process. But, despite this, there will still be an "unavoidable delay" of at least two months. Computer techniques are unlikely

to help, at least in the short term.

Foot and Mouth Vaccine

A NEW factory has been built at Grossburgwedel, outside Hanover, for the production of foot and mouth disease vaccine. The factory, which was planned, built and ready for operation within one year, is the seventh link in a chain of production units established by the Wellcome Foundation Ltd to meet demands from those countries where control measures are based on vaccination. It was opened on November 17 by Dr Fred Wrigley, deputy chairman of the foundation.

Vaccine will be produced at Grossburgwedel by a suspended cell culture technique developed by Wellcome which permits bulk production. Vaccine against those types of foot and mouth disease virus known to occur in Germany will be produced, but facilities are also available for switching production to other virus

types at short notice.

The new unit, which cost about £0.5 million, covers an area of some 40,000 sq. ft. and comprises three sections. Vaccine is produced in the main laboratory building and filled and packed under a rigid control system. Vaccine is tested under the control of a government veterinary officer in the testing station, which is the second section; the third section is a quarantine stable which provides accommodation for cattle and pigs. The research team at Gross-burgwedel will be led by Dr Rolf Bandau.

Foot and mouth disease vaccine is also produced in Wellcome factories in Spain, Kenya, Uruguay, Argentina and Brazil. In Britain and Eire, unlike other European countries, vaccination against foot and mouth disease is not used. It will be interesting to see whether the British Government will be compelled to change this policy by the current epidemic, still spread-

ing.

Relaying Telegrams

THE General Post Office recently opened in London a new telegraphy relay centre, designed to speed up the transmission of overseas telegrams. As well as sending out cables which originate in the United Kingdom, the centre, at Cardinal House in Farringdon Street, will also handle the large quantities of telegrams which simply pass through London on their way from, say, Montreal to Sydney.

The new system is almost entirely automatic, but because automatic routing requires an extra line in the message—equal in length to 10 per cent of the average cable provision is made for manual routing for telegraph administrations unwilling to pay extra. Messages arriving at Cardinal House are stored temporarily in ferrite stores and, if there is a suitable line available, are retransmitted immediately. If there is no line available, the messages are stored on magnetic tape to wait for a suitable line. The ferrite stores are small—2,000 characters—but the tape stores have a capacity of 40,000 characters each, and can if necessary accumulate messages over a period of hours if any outgoing line is out of action. Messages stored in this way are retransmitted in order of priority. system replaces a much cruder arrangement at Electra House in which cables were punched out on tape, torn off manually and retransmitted on another machine.

The GPO is now looking forward to the ideal system—still ten years away—which would be automated from start to finish and controlled by computers. As well as routing the cables, the computer could also be used to work out the bills.

More Fire-raising

Fire Research 1966, published on October 17, is the annual report of the Joint Fire Research Organization of the Ministry of Technology and the Fire Offices' Committee. This partnership between government and insurance came into being for the purpose of carrying out research into all aspects of fire and the danger it represents to both life and property.

According to the report, the direct fire losses are of the order of £75 million a year, with a further £75 million in indirect losses. In addition to this, the fire brigade service costs about another £75 million. The size of fires has on an average decreased, but there are now considerably more of them.

The Fire Research Station, which costs £300,000 a year to run, carries out research and also undertakes a great deal of testing for industry, government and insurance. A study of the statistics of incendiarism suggests that more fires may be caused by arson than are reported, and, moreover, the cost of these fires is likely to be greater than for fires started by other means. Of the ten most recent fires estimated to have cost £1 million each in direct fire loss, three have been attributed to incendiarism, six to unknown causes and one to smokers' requisites, as they are called.

The ratio of fire load to ventilation is an important factor in the extent of damage to structures and it is possible that the spread of fire in warehouses could be reduced or even prevented by providing water curtains. Smoke detectors have been found to give a much more rapid response than heat detectors, and there is evidence that a substantial reduction in fire losses could

be made by the provision of efficient early warning systems.

A new method of protection has been developed in the chemistry and chemical engineering section for protecting industrial equipment which contains sparking components or flames. The method involves incorporation of flame arresters in the casing of equipment so that, if an explosion should occur in the casing, the pressure is relieved through vents but flame does not spread to the outside; this, it is hoped, may result in a saving of £250,000 per annum.

Parliament in Britain

Students

THE Secretary of State for Education and Science, Mr P. Gordon Walker, gave the provisional number of full-time registered students in the universities of the United Kingdom on October 31, 1967, as 199,372, of whom 37,614 were new entrants to undergraduate and lower level courses. These figures compare with 184,510 and 54,058 respectively in the previous year. In addition, in Northern Ireland there were 5,230 students, including 1,489 new entrants, compared with 5,025 and 1,399 respectively in the previous year. (Written answer, November 16.)

Machine Tools

MR A. WEDGWOOD BENN, the Minister of Technology, stated that the National Research Development Corporation was managing on behalf of the ministry a scheme intended to encourage the wider use of numerically controlled machine tools. The scheme enables suppliers to offer machine tools to customers on a sale or return basis. Twelve manufacturers were participating in the scheme and three machine tools had been sold and delivered, with further sales in prospect. The scheme was capable of supporting sales to the value of £3.5-£4 million, but the response from users had so far been very limited. Mr Benn also stated that the Ministry of Technology was helping to establish low-cost automation centres at universities and technical colleges throughout the UK. (Written answer, November 10.)

Equipment Grants

BARONESS PHILLIPS said that the total amount of grant authorized for university expenditure on furniture and equipment in the current financial year was £25.5 million, and by July 1967 the universities had drawn about £8.5 million. Total drawings to date were about £14 million. (Answer, November 16.)

Research

In 1966-67 the Ministry of Technology spent £238 million on research and development in industry and within its own establishments. Dr Jeremy Bray, who gave the figures, said that the Government's policy was to place as many research and development contracts as possible in development areas, including Scotland. Total expenditure on research and development by the Ministry of Technology/Ministry of Aviation in 1966-67 was £289 million, of which £53 million was spent in the combined departments' establishments. Expenditure by industrial research associations in the financial year ending in 1966 was £13·2 million, and Government grants to the associations totalled £3·2 million. (Answer, November 14.)

Large meeting hall and library at Carlton House Terrace.

Moving House

The Royal Society has now completed its move to new premises at Carlton House Terrace, and the rooms were opened on Tuesday by the Queen, who is Patron of the Society. During the three centuries of its history the society has occupied six different sets of rooms, the most recent being at Burlington House, where it has been since 1857. The new rooms, built between 1829 and 1832 to the designs of John Nash, are part of a fine terrace with an imposing array of Corinthian pillars stretching the full length. The terrace faces St James's Park and the Mall, and the society will be occupying the four houses at the eastward end of the terrace, ending at the Duke of York's steps.

The striking appearance of the houses from the outside has been preserved, but inside there has been a radical rebuilding, including, in the case of number 9, the replacement of most of the load bearing walls below ground level. By removing walls, a lecture theatre capable of seating 250 people has been constructed in number 9, and the society's library will take up all the deep basements and all the first floor at number 6. All four houses have been knocked together to form one unit, modern heating and air conditioning have been installed and lifts and remodelled staircases have been built. Although the whole task could have been accomplished more cheaply by knocking down the old terrace and building anew, this would not have been

Much of the internal decoration, in a variety of styles, has been retained. The history of the houses is varied. Number 6 was once occupied by a Buenos Aires millionaire, Mr C. H. Sandford, who installed interior decoration of the most elaborate sort-mother of pearl ceilings, and Spanish and Florentine carvings and inlays-at the end of the nineteenth century. More recently, numbers 8 and 9 had housed the German Embassy in the era of Von Ribbentrop, and still bore traces of the taste of the Third Reich. Lord Holford, the architect for the conversion, barely conceals his feelings. In an article written for the society's own publicity, he describes the decoration: "Although it was not in a style (or mixture of styles) that would have been preferred by the Royal Society, or by any other learned society in the middle of the twentieth

century, much of the existing decoration had to be retained". The basements, he says, were dungeon-like and the construction of the buildings indifferent. Only unusual advantages of situation and environment

justified the conversion.

The society first showed an interest in moving to Carlton House Terrace in 1961. Originally it was thought that only Nos. 7, 8 and 9, with the basement of number 6, would be needed. In 1963, the Chancellor of the Exchequer gave his approval, announcing that the Government was prepared to pay the rent and annual maintenance for the 99 year lease of the four houses. The cost of conversion, then estimated at £500,000, was to be paid by the society. The floor space, 72,000 sq. ft., is more than two and a half times what was available at Burlington House. Furthermore, the President, Executive Secretary, and caretaker will all have flats in the new premises. (The present President, Professor P. M. S. Blackett, whose home is in London, will not be moving into his.) But the costs of the move were soon seen to have been underestimated, and they rose to £1 million. By making a variety of economies, the bill was reduced to £662,411, but further increases since then have increased it again, to some £850,000. Of this money the Nuffield Foundation gave £250,000, the Government £125,000 and the Wellcome Trust £103,000. Despite a number of smaller benefactions, the full amount has yet to be collected.

The Royal Society's move has brought comfort to others than its own fellows. The premises which it has vacated in Burlington House are now being divided between a number of societies. The Chemical Society of London has inherited the lion's share of the old apartments (and has launched an appeal to equip them properly). The Royal Astronomical Society, much cramped in recent years, has acquired some breathing space. Yet there remains among the societies a somewhat depressed nostalgia for the old dream of one building for all the learned societies in London.

Universities for Reform

The first private meeting on November 17 of the Academic Advisory Committee organized by the Committee of Vice-Chancellors seems to have been not merely a success but a landmark in the development of relations between British universities and British schools. One of the participants said afterwards that he had been astonished. "I had not expected anything like this." The outstanding feature of the proceedings seems to have been the unanimous agreement that the basis for selection into universities must be changed. In the process, the proposals put forward by the Schools Council for changing the present system seem not to have found many supporters.

Those present at the meeting in the Senate House of the University of London included most of the vice-chancellors of the British universities as well as academics nominated by the university senates. The chairman was Dr D. G. Christopherson, chairman of the Committee of Vice-Chancellors, and the audience ran to about 100. The proceedings were opened by Dr Geoffrey Templeman, Vice-Chancellor of the University of Kent and a member of the Schools Council, who described the origins of the Schools Council's proposal for a reform of the sixth form curriculum. A document embodying these proposals has already been circulated to the universities and will be published in the near

examined studies of a sixth form pupil should be restricted to two Advanced level subjects, and that there should be internally moderated courses (called "electives") as well

The nub of the scheme is that the externally

"electives") as well.

The surprise at Friday's meeting seems to have been the way in which the principal speakers, like those who followed them from the floor, argued in favour of a broader curriculum and against what seemed to them to be the narrowing character of the proposals of the Schools Council. The ball was set rolling, from the platform, by Professor J. T. Allanson of the University of Birmingham, who argued that the preparation at school for a scientific education should be more liberal; he would see the present pattern of three A-levels broadened to include at least four courses in the sixth form. Professor J. G. Wilson followed next, with the argument that the pattern of entrance to universities determined by performance in three A-level courses is one of the reasons for the drift from science to the arts subjects; in his view, too, the Schools Council's scheme would hinder and not help. The same theme seems to have been echoed at the conference by Mr J. Morrison, Principal of University College, Cambridge, who argued instead in favour of a pattern of five courses in the sixth form, spanning the arts and the sciences. By all accounts, this was very much like the scheme which Mr Morrison described at the Cambridge conference reported in Nature on September 23, 1967.

One experienced and philosophical observer of discussions among university representatives on academic policy said after the meeting that it was a great surprise that "not one voice was raised against the general character of the objections against the Schools Councils' proposals". The general opinion seems to have been one of sympathy with the objectives of the Schools Council, but scepticism about its methods. Dr F. S.

British universities seem prepared for change in entrance requirements.

Dainton, Vice-Chancellor of the University of Leicester, is known to have supported Professor Wilson's argument. Vice-Chancellors Aitken, Swann and Edwards (of Birmingham, Edinburgh and Broadford) are known to have intervened in favour of a broadened curriculum. Lord Annan (né Noel Annan) seems to have come out on the side of the angels in a characteristically impish way.

Professor Bryan Thwaites argued strongly at the conference for a course in mathematics designed for all students in British sixth forms. By all accounts, Professor Thwaites's proposals have already been put to the Schools Council, but the appropriate committees seem so far to have been unable to resolve the differences between the pure and the not-so-pure mathematicians, with the result that the council has not yet embarked on the development of the appropriate curriculum. The view at the meeting seems to have been that if compulsion of any kind is to be imposed on students leaving British schools, courses in mathematics and English should be obligatory.

What will this mean for the universities? One view, championed by Professor L. R. B. Elton (University of Surrey), was that the universities should somehow be able to accommodate more liberally educated entrants within their present three-year pattern of undergraduate courses. There seemed, however, to be more support for the notion that a more liberal sixth form would bring with it the need for four year courses. On this occasion, the universities seem to have been less readily disposed than on previous occasions to assume that such a development is unthinkable on financial

grounds.

The day's discussion seems, by all accounts, to have been splendidly capped by a stirring speech from Professor C. C. Butler (Imperial College), who urged the need for reform and the need for an evolutionary approach to it. He did not think that the British system could be made to change overnight, and he urged that the universities should collaborate with the schools in a number of experiments designed to test the feasibility and the advantages of different patterns of entrance qualifications. What he has in mind, by all accounts, is a series of experiments in which selected groups of schools would be encouraged to embark on alternative patterns of sixth form work in return for an undertaking by the universities that pupils so involved would not be handicapped in seeking entrance to universities.

But a heady day plotting reform does not mean that everything will now be different. For one thing, there is no certainty that the opinions of the university representatives last week will be confirmed by university senates, which are being asked by the Vice-Chancellors' Committee to submit their first comments on the proposals of the Schools Council by the end of this year. Early in the new year there is likely to be a discussion within the Standing Conference on Entrance to Universities from which, with luck, there may emerge a co-ordinated university view to put to the Schools Council by the spring of 1968. On the present showing, it seems very much as if this reply will take the form of an alternative proposal.

AND VIEWS

about the Cosmic Microwave Background

vidently something of a boom in studies ural phenomenon known as the cosmic background. This issue of *Nature*, for ntains no fewer than four articles on various

aspects of the subject. Elsewhere, the first results are beginning to appear of the refined methods of measurements designed two years ago when it was first recognized how tangible and how potentially important the microwave background may be. The group at Princeton University, for example, has within the past few weeks reported measurements of the background intensity at wavelengths between 8 mm and 10 cm which imply more certainly than previous measurements that the electromagnetic spectrum does accurately correspond to that of a blackbody. that the temperature obtained by this group—2.7° K is somewhat lower than that reported from other laboratories, usually with longer wavelengths, so that there is still room for argument on the central issue of whether the microwave radiation which seems to pervade the universe does indeed correspond to blackbody radiation, but this is unlikely to be an important The uncertainties of measurement are still great enough to make the comparison of measurements made by different instruments a somewhat hazardous undertaking.

That said, there is obviously a great deal to be learned from the studies of the microwave background which are already under way. The detailed study of the isotropic character of the radiation is obviously of the greatest interest. The point here is that the motion of the Solar System through the microwave background should be reflected in an anisotropy of the measured background. In other words, the apparent temperature of the radiation should vary from one direction to another. Hitherto it has been supposed that this phenomenon would be determined largely by the speed at which the Solar System is moving as a consequence of the rotation of the galaxy—a speed of 300 kilometres a second or thereabouts. The interest of the argument by Drs Stewart and Sciama (see page 748) is that it shows how the same kinds of measurements may throw light on the structure of the universe on a somewhat larger scale. In particular, sufficiently refined measurements of the microwave radiation may be able to suggest whether the local cluster of galaxies is rotating, and at what speed. The authors of this argument may have underestimated some of the difficulties of making precise measurements of the background—the problems are concerned not so much with the design of instruments as with the elimination

of external sources of interference. But the prospect which they offer is exciting.

This, however, is only one of the possibilities now to be followed up. The possibility of an interaction between fast electrons in the cosmic rays and photons of the microwave background is intriguing and potentially important. For sufficiently fast electrons, for example, even a sea of radiation corresponding to a temperature of 3° K or thereabouts would be practically opaque, which has led to the suggestion that there should be a limit to the energy of the cosmic rays, which can reach the Earth. But with the cosmic rays, as with the radiation itself, the search for anisotropy may be profitable. Evidently the boom in the microwave background is only just beginning.

Measurements and Standards

from a Correspondent

A CONFERENCE on radio-frequency measurements and standards was held in the Glazebrook Hall at the National Physical Laboratory last week. The Institution of Electronic and Radio Engineers, in collaboration with the Institution of Electrical Engineers, organized the conference to coincide with the inauguration of the British Calibration Service. Following the opening by Sir Leonard Atkinson, president elect of the IERE, eighteen scientific papers were read by authors from government, industrial and university backgrounds. The British contribution to the science of r.f. measurement in the range 100 KHz–1GHz was particularly stressed.

Development of techniques, comparable with the best available internationally, was the keynote of two contributions from the Electrical Inspection Directorate of the Ministry of Technology. The papers covered the design of a precision bridge and outlined methods for carrying out both attenuation and power measurement to a high degree of accuracy. A paper entitled "Noise Source Calibration in the Decimetre Band" described work carried out in the Services Valve Test Laboratory which, when coupled with a complementary paper from Ferranti Ltd. Edinburgh, on a noise source primary standard, set up new and improved standards for noise measurement.

Novel solutions to a number of problems appeared in the contributions from industry. Marconi Instruments put forward a design of co-axial thermocouple and associated r.f. load using thin film techniques which can be used to measure r.f. power to an accuracy of 5 per cent from below about 1 GHz, as the basis for a new range of commercial absorption power meters. In the measurement of lumped immitance, Wayne Kerr out-

lined the so-called crevasse entry technique and showed its corresponding impact on design of r.f. bridges.

In describing a technique for measurement of impedance within a micro-circuit module, authors from the University of Southampton showed how they had been able to achieve a satisfactory connexion between circuit and measuring bridge by use of a micro-strip line. Certain authors chose to support their papers by practical demonstrations of relevant equipment. It was interesting, after a paper on attenuation measurement, to see Russian and American standard attenuation measuring equipment compared side by side.

Whilst the conference succeeded in its prime aim of highlighting British work on r.f. measurements, it must be regretted that no corresponding European contribution was forthcoming.

New Way of Looking at Plants

The scanning electron microscope, with its wide depth of field giving almost three-dimensional pictures, is clearly going to be very useful to botanists. At the meeting of the Linnean Society on November 16, Dr P. Echlin described some of the techniques being developed for use with this microscope, and Professor V. H. Heywood showed how these techniques can be particularly valuable to the taxonomist.

The advantage of the machine is that whole specimens can be viewed rather than the sections which are necessary with the transmission electron microscope. Dr Echlin and his colleagues at the University of Cambridge are looking for the best ways of fixing the specimens, which he had classified as robust dry, robust wet and labile. Robust dry specimens, such as pollen grains, seeds and fruits, can be glued directly on to a clean surface. Dust, which will show up in the pictures. is a considerable problem, and at Cambridge a vacuum pump is used as a mini-vacuum cleaner to keep specimens as clean as possible. The robust wet specimens. which include diatoms and some algae and microfossils, can be placed without glue on to a surface and dried in a dust free atmosphere. Labile specimens present most problems, and although they can be dried by more conventional methods, such as passage through a series of alcohols, freeze drying has proved the most successful. Dr Echlin has developed a technique which involves dipping specimens into isopentane or 'Freon 22' cooled in liquid nitrogen. Using this technique, Chlorella can be fixed without collapsing. as it does when dried by more conventional methods. Blue-green algae and bacteria are also successfully fixed in this way.

Although the scanning electron microscope can give little information that cannot be obtained from serial sections in the transmission version, the use of whole specimens makes investigation very much easier. In one hour, perhaps five or six pollen grains or fruits can be examined and photographed. This is valuable for people such as Professor Heywood and his team at the University of Liverpool. They are conducting a taxonomic study of the tribe Caucalidae of the Umbelliferae, and are collecting characters from as many parts of the plant as possible. When examining the fruits for distinguishing characters, and having found more than forty with little effort, the team began to use the scanning electron microscope. This is revealing many

The apex of a main spine on the fruit of Torilis leptophylla (x 1,250).

features of the ridges, hairs and spines of fruits which were previously not seen, or were seen but not understood. These are features such as the apex of the spine on the fruit of *Torilis leptophylla* which is shown in the photograph. *Turgenia latifolia*, for example, has revealed surface projections on the fruit which are unique to the species.

Now that taxonomists are finding more characters than ever before, they have the problem of handling all this information. To begin with, a new terminology is needed to describe the surface features of the fruits, seeds or pollen grains. Methods of scoring and processing the data which are being so effectively recorded have also to be developed before the full value of the new techniques can be appreciated.

Elementary Genetic Control

from a Correspondent in Cell Biology

Factors which control gene activity of necessity control development. They are elusive, but there are indications that the control of some chromosomal genes is the product of some structural feature of the chromosome itself. There is one well known example—in female mammalian cells genes on one of the two X chromosomes are inactivated because one of the chromosomes becomes condensed or heterochromatic. Whether the paternal or maternal X chromosome is inactivated in this way is a matter of chance.

This process of inactivation has been explored by Cattenach and Isaacson (Genetics, 57, 331; 1967). In 1965 Cattenach showed that when part of the autosome carrying some of the genes controlling coat colour is inserted into one of the X chromosomes (X^T), these genes may be inactivated, but to a variable degree. One result is that two lines of mice with distinctive coat colour patterns can be selected and the stability of the inactivation studied directly by breeding experiments. In practice the inactivation of X^T is found to change on passage through several generations. Cattenach and Isaacson account for this change in the state of gene activity by proposing that there is a "controlling element" on the X chromosome which

influences the inactivation of the genes on the inserted segment, most probably by influencing the degree of heterochromatinization of the inserted segment. The same experiments demonstrate that the potency of the

controlling element can vary.

Similar changes of the state of genes have been followed in maize. McClintock (Carnegie Inst. Yearbook, 65, 568; 1966) has shown that pigmentation in certain tissues of maize is not regularly inherited, which suggests a modification of gene control in the germ line—as Cattenach has suggested for the mouse breeding experiments—or in early embryonic growth. There are also parallels with certain models for the regulation of genes in bacteria.

In maize as well as mice, heterochromatin is implicated in the mechanisms for gene control. In the fruit fly it is possible to influence the degree to which gene loci, seen on the bands of salivary gland chromosomes, can be made heterochromatic by varying the temperature at which the flies develop. Hartmann-Goldstein (Genet. Res., 10, 143; 1967) finds correlation between cold-induced heterochromatinization of bands locating genes for two morphological characters and the reduced expression of these genes. Her work shows how gene activity can be manipulated experimentally by altering chromosome structure. But if the controlling elements are heterochromatin, then it may be possible to influence their activity by environmental change. With this in mind, Mikula (Genetics, 56, 733; 1967) showed that day length can cause a heritable change at the R locus in maize. Such findings may seem heretical, but if genetics is to be of full value in developmental studies then phenomena like these must be fully understood.

Single Cell Proteins

from Dr A. C. Frazer

MORE than 400 people from 22 different countries took part in a three day discussion on single cell proteins at the Massachusetts Institute of Technology from Opening the conference, Dr Nevin October 9-11. Scrimshaw emphasized the urgent need for more protein to feed the ever-increasing population of the world. The problem, he said, could be met in several ways, such as reduction of current wastage, increase of local production, or the development of new sources of protein, either from plant sources or from fish, or by synthesis in single cell systems. No one method should be regarded as a panacea. Although the need was now recognized by responsible people, the urgency of the situation was not yet fully appre-

The background was presented by leading authorities in the fields of global food production and distribution, protein needs, and the agricultural and economic aspects of low cost protein production. The conference reviewed the various forms of single cell systems that might be used for protein production—yeasts, algae, fungi and bacteria. The biological, engineering and other problems relating to protein production in these various systems were presented. The basic raw materials to be used in these systems were also considered; these included agricultural and industrial waste materials and petroleum products. The safety evaluation of the protein produced by single cell systems was discussed. Although a considerable amount of work seems to have been done, there was some hesitation in putting the available facts fully before the meeting.

The next phase of the meeting was concerned with the practical experiences of people who had used some of these products for feeding studies in human subjects and in animals. The results appear to be promising. Several speakers stressed the importance of studying the acceptability of the various protein products, and there is little doubt that there is an urgent need for an adequate educational programme which will enable people to have a better understanding of the value of protein foods and also train those concerned in the

proper use of additional protein supplies.

In these discussions, it was apparent that there are two main approaches. One is conservative and aims to supply more low cost protein in animal feeds, so that the contribution to human nutrition is indirect. The other aims to increase the human protein intake directly. This could be done by supplementing existing foods with protein material or even by converting a new source of protein into analogues of conventional protein foods. Whatever may be the outcome of present research, there is little doubt that any new protein product will have to compete successfully with others which become available and with those already on the market. Although it is true that the economic factors concerned in producing a new substance change as development proceeds, it is the market-place which eventually decides the future of any new product. Many times during the conference it became clear that local factors might well be decisive in determining which type of protein supplementation was possible and—if a single cell system were used—which raw material would be economically feasible. In general, transport costs seemed likely to be a limiting factor.

A great many interesting and important issues were raised during this conference and the proceedings will be published in the near future. Perhaps the most encouraging feature was the fact that there is a worldwide interest in these problems and that many developing countries are beginning to play an increasingly active part in solving the practical difficulties. This kind of participation by developing countries in improving protein production and distribution is necessary for the future welfare of mankind.

Assembly of Quaternary Structures

from our Molecular Biology Correspondent

Most proteins contain several polypeptide chains. Most commonly, there are two types of these sub-units, which are under separate genetic control. The manner in which the rates of production of the sub-units are geared to each other, and the mechanism by which the finished protein is assembled, are matters which have until quite recently been altogether obscure.

In the archetypal case—haemoglobin—which is made up of four sub-units, two α and two β , so that its structure may be written $a_2\beta_2$, it was reported that completed a-chains are found attached to polysomes. This observation and its implications for the regulation of haemoglobin synthesis have been followed up by Baglioni and Campana (Europ. J. Biochem., 4, 480; 1967). They have found, by pulse-labelling experiments, that there are two polypeptide intermediates in rabbit reticulocytes; these have been identified by chromatographic properties as completed a-chains and free globin. By treatment with detergent the a-chains are released from the ribosomes, and are found to be free of tRNA. It therefore appears that they must have been synthesized at an earlier stage, and it is convincingly surmised that these same ribosomes are in fact producing β -chains. The a-chains evidently combine with the β -chains while these are yet incomplete; the $a\beta$ complexes—that is to say, free globin in its usual dimeric state—are then released, combine with haem and finally associate to form the $a_2\beta_2$ tetramer. Labelling experiments indicate that the latter processes may proceed by way of intermediates containing less than their full complement of haem.

This last observation is in good accord with findings on the mechanism of the haem-globin reaction in vitro. Winterhalter and Deranleau (Biochemistry, 6, 3136; 1967) have found all three haem-deficient haemoglobin species in mixtures of haem with excess globin. The form in which two of the chains carry haem groups is the most prominent, and was isolated chromatographically. The molecule was shown indeed to be tetrameric, but with an increased tendency to dissociate to dimers at low concentrations. By addition of labelled haemin, and separation of the chains, it was established that the a-sub-units were the ones that had already contained haem groups.

The concept of a stable species containing only two haems between four chains receives independent support from the work of Heidrich and Schroeder (Biochim. Biophys. Acta, 147, 389; 1967), who find that when separated haem and globin are recombined, no less than 25 per cent of such a component is formed; it will combine with haemin only when incubated with the cyanide derivative (which is also the one used throughout by Winterhalter and Deranleau).

As it has long been known that globin synthesis is stimulated by added haem, the differential reactivity of the a- and β -chains may lead to an overall regulatory effect, whereby, for example, the synthesis of a-chains is regulated by the haem supply; the availability of the a-chains then makes possible release of the β -chains from the ribosome, with the formation of complete haemoglobin, so that effective synchrony is achieved. It is interesting to note, as Baglioni and Campana also point out, that the H-chains of immunoglobulins have been shown similarly to be released from the ribosome only after association with completed L-chains. This sequence may therefore constitute a general feature of the biosynthesis of sub-unit proteins.

Flagella Morphogenesis

from our Cell Biology Correspondent

CILIA and flagella from protozoan to mammalian cells have the same basic structural pattern. Two central microtubules surrounded by a ring of nine outer paired tubules run the length of the organelle, forming the basic 9+2 pattern of the axoneme. Where the axoneme enters the cell body, the two central tubules terminate in a basal plate, but the nine outer doublets are continuous with two of the three tubules in the nine triplets of the basal body.

What specifies this very exact structure? Electron microscopy has shown that the basal bodies somehow

act as organizers for the axonemes, but that, of course. leaves unanswered the question of the specification of the basal body structure. In several protozoans the pattern of ciliation on the cell surface appears to be controlled by extranuclear genes, and there are several reports—the latest from Smith-Sonneborn and Plaut $(\hat{J}. Cell Sci., 2, 225; 1967)$ —that basal bodies, like mitochondria and chloroplasts, contain DNA. This immediately raises the possibility that basal bodies are self-replicating organelles in the sense that the DNA could act, no matter how many steps of RNA and protein synthesis intervene, as an organizer for the sub-unit protein of microtubules and perhaps even specify the microtubular protein as well. But it is far from certain that all basal bodies contain DNA. In the current Journal of Cell Biology (35, 323; 1967), Outka and Kluss suggest that in the protozoan Tetramitus rostratus the basal bodies are not self replicating and that in this species nuclear DNA, not basal body DNA, acts as an organizer for the assembly of flagella.

Tetramitus has, like the more familiar Naegleria gruberi, the very remarkable capacity of existing either as an amoeboid cell or as a flagellate and of transforming from one form to the other. Within two hours, amoeboid Tetramitus devoid of microtubules can change into a tetraflagellate cell with cytoplasmic microtubules and a "mouth" supported by a microtubular system. This flagellate form is stable; it both feeds and divides. Thus the transformation process provides a useful system for studying flagella morphogenesis.

The amoeboid Tetramitus is devoid of basal bodies and their formation is the first requirement of transformation. The problem, of course, is to recognize the very earliest stage of basal body formation. What Outka and Kluss have seen in the electron microscope is the association of recognizable developing basal bodies with amorphous material, which on morphological grounds they tentatively identify as unassembled microtubular protein. They have also seen striking and apparently transitory projections from the nucleus to the basal body. They reasonably interpret this as meaning that a nuclear gene product somehow seeds the assembly of microtubular protein into the ordered basal body structure and once this nucleation has occurred the flagella can grow, perhaps by self assembly.

Once the basal body has formed, a pocket of the cell balloons out from the cell surface above it, and, at the same time, axonemal microtubules develop from the basal body into the outgrowth. The central pair of the axoneme always appears before the nine outer doublets, which at early stages are randomly arranged before they become sequentially positioned in the outer ring. As the growing axonemal microtubules often terminate in fine filaments, and as similar filaments are scattered throughout the outgrowth, it seems likely that microtubular development involves first the production of filaments by linear aggregation of subunit protein and then their assembly into the wall of the microtubule.

In the absence of correlated biochemical or genetic studies, any interpretation of a dynamic cell process from a series of electron micrographs must be only tentative. Nonetheless, the structure and timing of the association between developing basal bodies and nuclear outgrowths clearly suggest that the nucleus may play a very direct part in flagella morphogenesis in some species.

Organization of Ministry of Technology

The following extracts were taken from the prepared text of a speech by Sir Richard Clarke, Permanent Secretary, Ministry of Technology, in Birmingham, November 21.

THE present Ministry of Technology really dates from February 15, 1967, with the merger between the industrial part of the seven year old Ministry of Aviation (the civil aviation side having already gone to the Board of Trade) and the two year old Ministry of Technology (started in October 1964). The Ministry of Aviation has not swallowed up the old Ministry of Technology: nor has the Ministry of Technology swallowed up the Ministry of Aviation. We have a new entity which is swallowing up both.

The department controls seven [government research establishments] from the old Ministry of Aviation (plus two factories) and nine from the old DSIR—a total staff of 23,000. If we include AEA establishments, the total R and D manpower is about 9,000 qualified (graduate equivalent) engineers and scientists, compared with 55,000 enguged nation-wide on R and D. In addition, the department supports 45 industrial research associations with about 1,800 qualified men (formerly supported by DSIR). It is responsible for the National Research Development Corporation, which had been with the Board of Trade from the outset in 1948 to end-1964, and is currently handling 184 development projects with an investment of nearly £22 million.

Change in Whitehall

Since the early 1950s, most of the six blocks of public business [controlled by the department] have been regrouped with others and restyled at least three times. All large organizations need built-in arrangements for change and adaptation; and most will benefit from one major restructuring every ten years or so. But three or four major reshuffles in fifteen years is a different matter.

The essence of this industrial work is to establish effective communication and mutual confidence between the department and the industry. These are not easy relationships to create and maintain, and repeated changes in the machinery of government make them much more difficult. The detailed work tends to continue to be done by the same people. But the movement of staffs from one department to another presents every time major problems of organization and human adjustments and career planning, and of building and rebuilding the personal relationships and loyalties which are the heart of organization. The benefits from change and regrouping, like those from all mergers, take time to secure and are slow to accrue. Too often there is not enough time to get the benefits from one major change of structure before the next change is made. Let me repeat that changes in the administrative structure of government may be very necessary, in order to reflect a change in the long-term content and direction of the government's relationship to industry. But there is a real price to be paid in terms of the hard efficiency of the work of the governmental machine and thus of the effectiveness with which governments can carry out their industrial policy.

I have been speaking so far of changes in departmental structure and organization, and thus of changes in the duties and responsibilities of ministers and senior officials. These are in addition to the changes of ministers and senior officials which take place in the normal flow of governmental reconstructions and civil service appointments. The two together have had quite striking results in the

years November 1, 1957, to October 31, 1967. In this period, there have been 4 ministers and 4 permanent secretaries in charge of the government's relationship with merchant shipbuilding; 8 ministers and 6 permanent secretaries for aircraft; 6 ministers and 4 permanent secretaries in charge of the government's relationship with the engineering industry. These ten years cover both Labour and Conservative administrations, and what I say applies equally to both. One cannot say whether this dilution of the personal responsibilities for the government's contact with these sectors of industry is a contributory cause or a consequence of the difficulty which this country has been experiencing in finding an effective relationship between government and industry since the early 1950s. But it must be important.

Technology/Aviation Merger

[By November 1966 the department had responsibility for computer, electronic, telecommunications, machine tool, engineering and shipbuilding industries.] Powerful arguments were being made also for bringing some of the responsibilities of the Ministry of Aviation into the new department. It made little sense to talk about strengthening the technology of industry without regard for one of the most advanced technologies of all and the one receiving most government support—the aircraft industry. biggest research establishments, with most technological "fall-out", were those of the Ministry of Aviation. It was ineffective for the Ministry of Technology to be trying to strengthen the electronic industry's structure, when the main government relationship with the industry was the Ministry of Aviation's massive procurement. All this added up to a decisive argument for the ministry to take over much of the responsibility for the Ministry of Aviation. This was announced by the Prime Minister in June 1966. The old Ministry of Supply saw its primary duty in defence, with the civil industrial side a poor second. The new department has a large and important defence supply function, but its centre of gravity is definitely on the industrial side and will remain so. The old idea has been abandoned that "science" should be kept at arm's length from the main government machine in order to preserve the integrity of research: the task is now seen as one of bringing industry and the government research establishments together in order to get the best possible cross-fertilization and market orientation: we now regard science and technology as being in industrial policy right up to the neck. Thus, we now see an articulated chain of government activity, linking together scientific and technological research and innovation, the problems of industrial structure, and the role of public procurement.

The New Department

I would like to say a little about the human beings who have this task to carry out. The civil service tends to be rather restrained in its references to itself, so that quite absurd caricatures tend to become accepted as revealed truth. We are a very large department, total over 36,000, almost all from the Ministry of Aviation, the Board of Trade and DSIR. The total is perhaps a little misleading, for our research establishments and factories account for

Table 1. NON-INDUSTRIAL STAFFS

	Total (rounded)	Head- quarters	establish- ments and factories	Inspec- torates
Administrative	150	150		
Executive	2,300	1.870	360	60
Clerical and typing	5,150	3,000	1,750	420
Professional I (1)	3,200	900	2,000	300
Professional II (2)	8,300	1,160	5,700	1,420
Ancillary technical (3)	1,750	400	1,200	150
Miscellaneous	1,050	520	520	10
Total	21,900	8,000	11,530	2,360

Scientists, engineers, chemists, accountants, etc.
 Scientific assistants, technical grades, experimental officers, draughtsinen, etc.
 Drawing office assistants, photographers, stores grades, telephonists, etc.

about 23,000 of the 36,000, and the inspectorates for about 4,000, with something over 8,000 at headquarters.

Included in the 36,000 are nearly every kind of skill. Over 13,000 are industrial workers; 1,000 are Service personnel; the 22,000 non-industrials are divided:

This is a great weight of experience and expertise; and we devote quite large resources to the job of managament. On this I must limit myself to two short points. First, career planning. This has always been well done for the administrative grade. The Ministry of Aviation was developing it effectively for scientists and engineers. The department now has 1,900 in the scientific grades, approaching double the old Ministry of Aviation. We see here a widening of the field of opportunity for our scientists, and a formidable but repaying task of extending career planning. Second, training. Here again we have a large operation from the old Ministry of Aviation, with central training in department-wide organizational, management and specialist courses; with group training for staffs in particular branches. It is difficult to show the scale by statistics. However, this year we trained over 1,000 of our staff in central management and specialist courses.

The Senior Staff

In terms of senior and highly qualified staff, the department is very large. We have about 70 earning £5,000 or more, which is about twice as many, for example, as the Treasury or the Board of Trade. These are about equally divided between (i) administrators, (ii) headquarters engineers and scientists and other specialists, and (iii) those in the research establishments. About one-quarter are under 50; and about one-quarter of the whole 70 reached this level at the age of 42 or less. These age averages are virtually the same for administrators, engincers and scientists alike; so the chances of an able man to get into the top group relatively young are probably about the same on all ladders.

In this top group of 70 there are 21 men and 1 woman of the administrative grade (under-secretaries and above). Half of them were at Oxford or Cambridge, but only 9 entered the administrative grade by the direct route from the university; 5 were promoted from lower grades, and 8 came into the civil service after experience outside. Nevertheless, they are highly professional: three-quarters of them have been working in or near the field of the present department ever since the War.

Lastly, I should mention the 11 top men in the department. These consist of 5 administrators—the permanent and second permanent secretaries and three deputy secretaries: one came up the ladder from the old Ministry of Supply/Aviation, one from the Board of Trade, two from the Defence Department and one from the Treasury. There are four controllers—Aircraft, Research, Guided Weapons and Electronics, Industrial Technology. One is an air marshal, a scientist who came into the RAF during the War: one is an electrical engineer, formerly head of the Royal Radar Establishment at Malvern: one is an aeronautical engineer, now president of the Royal Aeronautical Society: the fourth an electronic engineer from Aldermaston, who was made an FRS

this year. At the same level are the directors of the two senior research establishments, the Royal Aircraft Establishment at Farnborough and the National Physical Laboratory. These 11 are a mixed group, all in their fifties; two Scots and two Welsh and seven English; three from private boarding schools; six Oxbridge; eight graduates in scientific subjects and three in arts. Between them, they share a wide variety of background and experience, inside and outside the civil service, which is not easy to reconcile with the picture which sometimes gets painted.

Organization of the Department

Each of the three groups-Aviation, Research and Engineering—has a fairly clearly defined set of tasks to carry out. Some of these are self-contained: others impinge upon other groups and upon the links between the groups.

Research Group

[Having discussed the Aviation group, Sir Richard went on: I said earlier that the department's research establishments plus those of the Atomic Energy Authority, employ about 9,000 qualified engineers and scientists. This is the biggest force under one central direction in Western Europe; and our task is to deploy these resources to the best possible advantage of the national economy.

I have been talking here in terms of numbers—the of the government-financed establishments, and whether it should be increased or reduced and by how much. But it isn't just "How many?" It is also "How good?" It is important whether there are 8,500 or 9,000 or 9,500 qualified scientists or engineers in our research establishments. But it is much more important that they should be doing the right kind of work; and even more important again that the fruits of that work should go to where they can be used effectively for the benefit of industry.

Engineering Group

[Having spoken of the role of the five industrial divisions -electronics; computers; machine tools and manufacturing machinery; vehicles and mechanical engineering; shipbuilding, electrical and process plant-in fostering economic and technological development and competitive power, Sir Richard said:] This work brings us immediately to problems of industrial structure. In many parts of the engineering industry, we have become impressed by the disadvantages of smallness. Where R and D expenditure, and the much larger expenditures involved in bringing R and D into successful production, is important, the size of turnover over which the expenditure can be spread is highly relevant. IBM's R and D expenditure, though huge, is only about 5 per cent of its turnover. should not be so silly as to favour bigness for its own sake. A big organization may be just as sleepy as a small one. Mergers are valuable only if they are used to cut out dead wood. We have formed the opinion, however, that especially in the industries with a big component of advanced technology, larger units have their advantage. This is where the department's work fits in with the Industrial Reorganization Corporation, whose job it is to seek opportunities to stimulate constructive industrial re-organizations. Throughout the engineering industry, events are on the move. In shipbuilding, the mergers postulated in the Geddes Report are under way. In electrical engineering, we are clearly in a period of rogrouping. In machine tools, a number of large firms have emerged. We are getting, for better or for worsewould say for better-very large changes in industrial structure.

Conclusion

To sum up, we see our task as being to sharpon public awareness of the decisive position of industrial technology and productive efficiency in the attainment of all our national objectives.

Some Sociological Concomitants of Sixth Form Subject Specialization

by RONALD KING University of Exeter The choice between science and the arts at sixth form level may be conditioned by the social background of the pupil and his involvement in the school.

THE studies of Hudson indicate that there may be significant psychological differences between science and arts specialist students both at sixth form and university level. The sociology of subject specialization has received less attention, except at a purely speculative level, by those interested in the "short-fall" in science students or the "swing to the arts". A few empirical studies have intimated some of the social factors that may condition subject choice, as, for example, the recent study of Box and Ford which explores the role of the working class chemistry student in terms of the concept of marginality².

The empirical study reported here sheds a little light on the influence that a pupil's social background and the formal organization of the school may have on subject choice. The evidence is drawn from a larger piece of research involving pupils of all ages in a London boys' grammar school. In terms of its size, staffing ratio, proportion in the sixth form, examination success, qualifications of staff and social composition, the school was quite typical of boys' grammar schools as described in the Department of Education and Science statistics.

The case study was one of the social values and involvement of pupils in the school. A survey of the teachers indicated which values they purported to transmit to the pupils. This included their approval or disapproval of interests and activities in terms of their suitability for the pupils. A questionnaire administered to the pupils included items and scales designed to measure these attitudes, values and interests. Although the responses to each item were scored and analysed, it was also convenient to assign each pupil a score on a short four point scale (0-3) for the holding of values approved by the school. Involvement was measured by the attitudes of the pupils to different aspects of school, and their actual behaviour in terms of the frequency with which they joined school clubs. Each pupil was thus assigned a position on a four point scale (0-3) for involvement in the school.

The principal independent variables in the analysis were pupil age, social background and stream status. The most significant social background factor was found to be the pupils' parents' own experience of grammar school education. Thus pupils were classified as first or second generation grammar school pupils. The streaming in the school took the form of "expressing", in which the thirty most successful pupils at the end of the first year of school were given an accelerated course to take O-level in their fourth year.

The sample of sixth formers (n=99) represented virtually all the sixth formers in the school. Apart from analyses using the expressed/non-expressed, first generation/second generation dichotomies, analysis was also made in terms of subject choice—arts or science. Four social factors were found to be associated with this subject choice: (1) the educational experience of parents; (2) the incidence of expressing; (3) the extent to which a pupil held school-approved values; (4) the degree of the pupil's involvement in the school.

Table 1. ARTS AND SCIENCE SPECIALISTS BY EDUCATION OF PARENTS AND EXPRESSING

		Arts			Science		
	n	f	%	f	%		
First generation expressed Second generation expressed First generation non-expressed Second generation non-expressed	29 14 35 21 99	9 8 21 11 49	31.0 57.1 60.0 52.4 49.5	20 6 14 10 50	69·0 42·9 40·0 47·6 50·5		

The choice of science was particularly associated with first generation expressed pupils (P=0.02 by χ^2 , Table 1).

Wilkinson has shown that success in a subject at O-level often leads to further A-level study³. The results for science examinations at O-level for expressed pupils were very good in the subject school—thus the disposition for expressed pupils to continue science studies. Chown has shown that working class pupils in grammar schools rely mainly on their teachers for educational and vocational guidance4. These first generation, mainly working class, expressed pupils may have responded to the formal and informal guidance given by their science teachers because science subjects can lead to occupations of which the working class pupils can have some fairly specific image. Box and Ford see the choice of chemistry on the part of working class university students as a way of resolving their "crisis of identity". The bright working class student, estranged from his family by the changes his education has brought about in him, may embrace the role of professional scientist because this is seen as being marginal in its social class connotations, and so he can escape the middle class life-style which he perceives as his alternative ultimate destiny.

An analysis was made of the mean scores for values and involvement. Slight, but not significant, trends emerged. When a similar analysis was made of those fifth formers who eventually became sixth form subject specialists, similar, but still not significant, trends were found. By combining the results of the existing subject specialists with the eventual specialists, significant patterns did emerge (Tables 2 and 3). Specialization in science was associated with: (1) first generation expressed pupils

Table 2. MEAN SCORES FOR VALUES—ACTUAL AND EVENTUAL SUBJECT SPECIALISTS

	n	Arts Mean	S.D.	n	Science Mean	S.D.
First generation expressed	18	1·22	0·55	30	1·93	0·49
Second generation expressed	11	2·27	0·76	11	1·36	0·71
First generation non-expressed	30	2·10	0·67	24	1·26	1·20
Second generation non-expressed	16	1·81	0·58	18	2·11	0·45

Table 3. MEAN SCORES FOR INVOLVEMENT—ACTUAL AND EVENTUAL SUBJECT SPECIALISTS

	n	Arts Mean	S.D.	n	Mean	
First generation expressed	18	1·72	1·19	30	2·20	1·11
Second generation expressed	11	2·27	1·34	11	1·54	0·79
First generation non-expressed	30	1·84	1·01	24	1·17	0·74
Second generation non-expressed	16	1·56	1·23	18	1·67	1·06

highly involved in the school (P = 0.01 by t test); (2) second generation expressed pupils with low involvement in the school (P = 0.01); (3) first generation nonexpressed pupils of low involvement (P = 0.05); and poor school-approved values (P = 0.01).

These results clearly indicate that any differences associated with subject specialism may in turn be related to the social origins, school experience and value-set of the specialists concerned. Further results of this study do, however, reveal features of sixth formers which seem to relate directly to their chosen subject. (These differences have been shown not to be associated with the different social compositions of the arts and science groups.)

Science students were found to be less sceptical of textbooks, subject teachers and scientific laws as authoritative sources of information. Science at the intermediate level deals with certainties rather than speculations. The trust of textbooks and teachers reflects the emphasis on facts and exact procedures in sixth form science. In their assessment of the qualifications of teachers they "got on well with", science students stressed clear exposition on the part of the teacher rather than any special personal pupil/teacher relationship. Their acceptance of scientific laws forms the basis of much intermediate experimental work and calculation problems.

Science students read less than arts students. They joined fewer school clubs and this certainly contributed to their being made prefects less often. Like the scepticism differences, these too may be associated with the nature of science at the sixth form level, as well as the general pressure of school work felt by these young science specialists, most of whom (74.0 per cent) hoped to go to university (compared with 53.0 per cent of arts specialists).

It is possible that a student's experience of a subject will be conditioned by his expectations of that subject, and these will probably be related to the kind of social factors already discussed. It is possible that pupils with socially determined need-dispositions, like the establishment of a social identity, select subjects which seem to fulfil these needs. Finally, it is clear that any logistical analysis of the supply of scientific manpower will need to take into account the kind of social factors outlined and discussed here.

This research was supported by the Central Research Fund of the University of London.

Peculiar Velocity of the Sun and its Relation to the Cosmic Microwave Background

by

J. M. STEWART D. W. SCIAMA

Department of Applied Mathematics and Theoretical Physics, University of Cambridge

If the microwave blackbody radiation is both cosmological and isotropic, it will only be isotropic to an observer who is at rest in the rest frame of distant matter which last scattered the radiation. In this article an estimate is made of the velocity of the Sun relative to distant matter, from which a prediction can be made of the anisotropy to be expected in the microwave radiation. It will soon be possible to compare this prediction with experimental results.

Until comparatively recently, the science of cosmology was based on one experimental fact, the recession of extragalactic objects. The theories used to explain the expansion of the universe usually assume that the universe is homogeneous and isotropic, and number counts of galaxies, radio galaxies, etc., in various regions of space have been made to check these assumptions to varying degrees of accuracy, and also to refute some theories which were in conflict with the observations. There has been, however, an important recent observational development which is the discovery of the excess microwave background¹, assuming of course that it is cosmological in origin². While there are still doubts as to its exact effective temperature, it is certainly highly isotropic3. Thorne has suggested4 that the isotropy of the microwave background gives a very strong restriction on the possible anisotropy in the early stages of the universe, while Misner⁵ has pointed out that neutrino viscosity could make the present isotropy (or lack of it) independent of still earlier conditions.

In this article we shall discuss that component of the angular distribution of the microwave radiation which has a 24 h period in any plane. Throughout the rest of this article, anisotropy refers only to this component. Then the radiation defines a rest frame at our location in space, namely, that frame in which the radiation is isotropic. If the Sun is not at rest in this frame, its peculiar motion can be measured from the resulting anisotropy of the radiation arising from the Doppler effect. The best measurements to date show that the component of the Sun's peculiar velocity close to the celestial equator $(\delta = -8^{\circ})$ is less than 300 km/sec. Measurements in other directions and to greater precision should be available soon.

If the radiation is cosmological in origin, then the rest frame it defines is the rest frame defined by the matter which last scattered it. (We regard it as unlikely that any anisotropy of primordial origin should have a 24 h period.) This matter is extremely distant, because on the most conservative assumptions it cannot have a red-shift less than about 7, and the actual red-shift may be much greater. According to Mach's principle7 this rest frame of distant matter defines an inertial reference frame at the Sun. If we could estimate the motion of the Sun relative to this inertial frame, then we should be able to predict the resulting anisotropy in the microwave radiation. Partridge and Wilkinson³ pointed out that, relative to an inertial frame, the Sun rotates around the centre of the Galaxy with a velocity of about 250 km/sec, and they suggested that a relatively small increase in the accuracy of their measurements should reveal this rota-Any inertial frame chosen locally, however, could well have a uniform rectilinear velocity with respect to the rest frame of distant matter (although according to Mach's principle it could not have an angular velocity with respect to distant matter) and this would affect the

anisotropy prediction. If we choose as a reference frame a frame which is inertial and at rest relative to some suitably defined average of all nearby matter, then the larger the amount of matter considered, the more nearly our inertial frame should correspond to the rest frame of distant matter.

We consider here an inertial frame based on the local supercluster of galaxies. One of us made a rough estimate of the Sun's peculiar velocity relative to this frame, and we now want to give a more detailed discussion of this question. In particular, we wish to predict a range of directions in which the peculiar velocity of the Sun relative to this local inertial frame should lie. It will then be possible to compare these theoretical results with the observations, when sufficiently sensitive measurements of the anisotropy of the microwave radiation in all directions become available.

Motion of the Galaxy in the Local Supercluster

A study of the distribution of bright galaxies (see, for example, ref. 9) strongly suggests that the Local Group belongs to a supercluster of galaxies (Fig. 1). De Vaucouleurs has estimated that this supercluster is roughly a spheroid, with an axial ratio of 1:5, centred on the Virgo cluster of galaxies. The Local Group would lie near the central plane and at about two-thirds of the distance from the centre to the edge. The flattening of the supercluster suggests that it might be rotating about its axis through the Virgo cluster, and this possibility has been investigated by many authors, especially Rubin¹¹, Ogorodnikov¹² and de Vaucouleurs¹⁰.

away from Virgo, making it less than that predicted by the Hubble law (as determined from distant galaxies). A crude calculation shows that the difference is at most 100 to 200 km/sec. Because our tangential velocity is thus likely to be the major component of our total peculiar velocity relative to Virgo, it is most important to decide its sense, and if possible to obtain a better estimate of its We have therefore attempted to determine the differential velocity field in the vicinity of the Local Group by an Oort-type analysis of the radial velocities of nearby galaxies. If the Virgo cluster were not stable, however, then a substantial fraction of the mass of the supercluster could be distributed fairly uniformly in its plane, and we might have to contend with a rigid body rotation superimposed on the differential velocity field. A more sophisticated analysis would then be needed to predict the magnitude of such a rotation.

The analysis is similar in principle to that used in the Oort theory of the rotation of the Galaxy¹⁶, except that no proper motions are available, and allowance must be made for the substantial rate of expansion of the supercluster. There are unfortunately serious practical difficulties in analysing the motion of the supercluster: (a) the measured radial velocities are not particularly accurate, and it is well known that groups of galaxies have velocity

measured radial velocities are not particularly deceased, and it is well known that groups of galaxies have velocity dispersions which may be large enough to disrupt the groups; (b) we are concerned with distances in the range 1-8 Mparsec and the secondary distance indicators (HII regions, angular diameters, etc.) which have to be used in this range have significant random and systematic errors; (c) if we select only those galaxies which are close

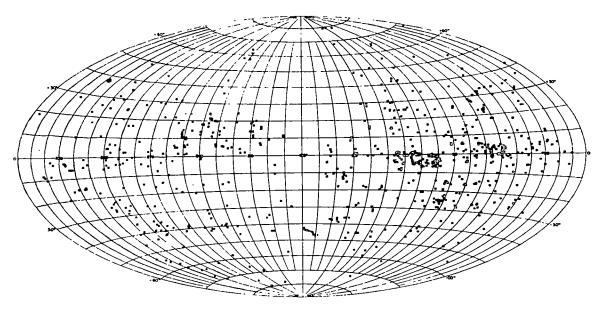

Fig. 1. Distribution of 2590 bright galaxies in supergalactic co-ordinates. Note the concentration to the supergalactic plane especially in the northern galactic hemisphere. (Source: ref. 9.)

Although Ogorodnikov's study¹² is based on data which are now obsolete, we shall adopt his qualitative result that differential velocities in the plane of the supercluster are an order of magnitude greater than those perpendicular to the plane. Thus we are essentially dealing with plane motion. If the Virgo cluster is stable and so has the mass (about 10⁴8 g) implied by the virial theorem¹³, the circular velocity at the position of the Local Group would be ~770 km/sec (if its distance from Virgo is 11⋅5 Mparsec¹⁴). The gravitational effect of the Virgo cluster could also affect our radial velocity

enough for the usual first-order theory to apply, then there are too few galaxies to obtain reliable results. If we include more distant galaxies, a higher order theory must be used, and there will be too many undetermined parameters in comparison with the amount of data available. Because the distances to the galaxies are so poorly determined, it does not seem worthwhile to use more than the simplest first-order analysis. We have made such an analysis, using the results of de Vaucouleur's recent study¹⁴ of the grouping of galaxies within the supercluster.

We introduce cylindrical polar co-ordinates (ρ, θ, z) fixed with respect to the supercluster, and with the axis along the supercluster axis through Virgo. Let the components of the velocity of the local standard of rest be (π, θ, Ez) , where E is the local Hubble constant for velocities perpendicular to the supergalactic plane. In defining the local standard of rest we have made allowance both for the rotation of the Galaxy and for its peculiar motion relative to the Local Group. We have also used the assumption mentioned earlier, that there is no peculiar velocity in the z-direction.

and D is not much greater than $(A^2+C^2)^{\frac{1}{2}}$, which was certainly found to be the case by Ogorodnikov¹², then the term proportional to D can be neglected. Also because E is presumably not significantly greater than K, this restriction on B means that the term involving E can be neglected.

Following de Vaucouleurs¹⁴, we have classified into groups all the galaxies with $|B| \lesssim 20^{\circ}$, and which lie outside the Local Group, but within 8 Mparsec (on the distance scale given by $H=100 \text{ km sec}^{-1}$ Mparsec⁻¹ for very distant galaxies); the details are shown in Fig. 2 and Table 1.

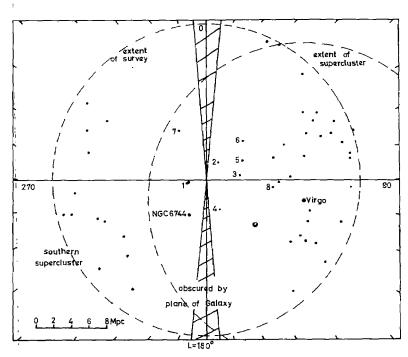

Fig. 2. Space distribution of nearby groups projected on to the supergalactic plane. The Galaxy is at the centre of the diagram. The numbers refer to the groups the members of which were used in the analysis (see Table 1). Data were taken from ref. 14.

Now if v is the radial velocity of a galaxy at a distance r from the Local Group with supergalactic longitude and latitude L and B, and if r is small compared with the dimensions of the supercluster, an Oort-type analysis gives to first order 15,16

$$\begin{split} v &= r \text{cos}^2 B(K + A \text{sin} 2(L - L_0) + C \text{cos} 2(L - L_0)) + \\ &r D \text{sin} 2B + r E \text{sin}^2 B + \delta v, \\ &= r \text{cos}^2 B(K + (A^2 + C^2)^{\frac{1}{2}} \text{sin} 2(L - L_0 + \varepsilon)) + \\ &r D \text{sin} 2B + r E \text{sin}^2 B + \delta v, \end{split}$$

where

$$K = \frac{1}{2} \left(\frac{\partial \pi}{\partial \rho} + \frac{\pi}{\rho} + \frac{1}{\rho} \frac{\partial \Theta}{\partial \overline{\Theta}} \right),$$

$$A = \frac{1}{2} \left(\frac{\partial \Theta}{\partial \rho} - \frac{\Theta}{\rho} + \frac{1}{\rho} \frac{\partial \pi}{\partial \overline{\Theta}} \right),$$

$$C = \frac{1}{2} \left(\frac{\partial \pi}{\partial \rho} - \frac{\pi}{\rho} - \frac{1}{\rho} \frac{\partial \Theta}{\partial \overline{\Theta}} \right),$$

 $D=\frac{1}{2}\frac{\partial \pi}{\partial z}$, $2\varepsilon=\tan^{-1}\left(C/A\right)$, L_0 is the longitude of the axis of rotation, δv is the residual velocity of the galaxy, and all derivatives are evaluated at the local standard of rest. Provided we restrict the data to low latitudes $(|B| \lesssim 20^{\circ})$,

For each group we have estimated a distance by considering the distance determinations for individual group members cited in Table 1. These were reduced to the distance scale for which $H\!=\!100~{\rm km~sec^{-1}~Mparsec^{-1}}$ for very distant galaxies, and a weighted average was used to give the distance of each group. Then for each galaxy we evaluated the effective Hubble constant

$$\frac{v\sec^2 B}{r} = K + A\sin 2(L - L_0) + C\cos 2(L - L_0) + \frac{\delta v\sec^2 B}{r}$$

A double sine curve was fitted to the data by means of a least squares analysis, and confidence limits were deduced for K, A and C by consideration of the residuals. There are two plausible ways of analysing the data; the simplest is to give equal weights to the brightest galaxies in each group. If, however, the groups are stable it is preferable to weight the data according to the masses of the individual galaxies, or according to their luminosities because all the bright nearby galaxies are spirals with roughly the same mass-luminosity ratio. (We also assume that the first brightest galaxies in the groups have roughly the same absolute magnitude.) Apart from the obvious dynamical reasons, this weighting is advantageous because it decreases the number of galaxies to be considered and lessens the error due to a non-member galaxy being included in a group. (Such an interloper would usually lie behind the group, and so would tend to be fainter than

the group members.) If, however, the groups are unstable this method will not remove the residuals effectively, because great weight is given to the brightest galaxies in each group. The data and the two fitted curves are shown in Fig. 3. From these we have deduced the following parameters.

	Equal weighting	Mass weighting
K (km sec ⁻¹ Mparsec ⁻¹)	91 (±6)	93 (±6)
A (km sec-1 Mparsec-1)	$-24 (\pm 8)$	$-22 (\pm 8)$
C (km sec-1 Mparsec-1)	$-8(\pm 9)$	$-9 (\pm 10)$
ε (in degrees)	$+9(\pm 11)$	$+11 (\pm 13)$

These values will be inaccurate because: (a) the radial velocities are poorly determined and include residuals: (b) the distances are probably very inaccurate (but apart from a scale factor the errors are probably random); (c) the linearized model is not a completely adequate description of the local kinematics. Provided that these errors are random and do not include any systematic effects, then the probability that K, A and C lie outside the limits given is <10 per cent. We might expect the real errors to be rather less than the quoted values for the following reason. The mass weighting is equivalent to choosing (for special dynamical reasons) a sub-set of our set of galaxies, without regard to their values of L and their Hubble constant, and giving the members of this sub-set equal weight. If our fitted curves contain large errors because of the scatter in the diagram, we could not expect the agreement between them to be as good as has been found. Because the two sets of values are roughly the same, we shall henceforth use the mass weighting values.

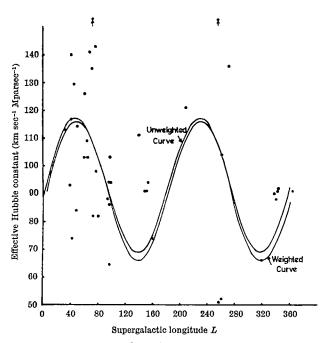

Fig. 3. The effective Hubble constant for nearby galaxies plotted as a function of supergalactic longitude L. The double sine curves were fitted by a least squares analysis. For details of the weighting, see text.

The next step is to derive the net tangential velocity of the local standard of rest from the differential velocity field we have just determined. This cannot, however, be done without further assumptions. We shall assume in the first place that most of the mass in the supercluster is concentrated towards its centre so that there is no rigid rotation superposed on the differential rotation. Second,

we note that the local value of A for circular orbits under the gravitational action of a mass of 1048 g located at Virgo would be about 50 km sec⁻¹ Mparsec⁻¹. of the same general order, though twice as large, as the value of A we have found from our kinematical analysis. We shall therefore assume that our actual tangential velocity, Θ , is related to our derived value of A in the same way as for circular orbits, that is

$$\Theta \sim \frac{4}{3} A_{\rm P}$$

$$= -340(\pm 120) \text{ km/sec}$$

As regards the peculiar radial velocity of the local standard of rest we cannot argue in an analogous way, because our value for C has the wrong sign for the differential expansion to be explained in terms of the retarding

action of Virgo. Presumably the supercluster is not completely relaxed. Nevertheless we can infer that the peculiar radial velocity is small, from the fact, stressed especially by Sandage (ref. 17, p. 378), that Virgo fits well onto the red-shift-apparent magnitude relation for the brightest members of distant clusters of galaxies. If we assume that the absolute magnitudes of the brightest galaxies in Virgo do not differ by more than ± 0.3 m from the corresponding means for all rich clusters, then we can estimate that our peculiar radial velocity is unlikely to exceed ± 200 km/sec.

We may note in passing that the expansion rate of the supercluster relative to the local standard of rest in the tangential direction is

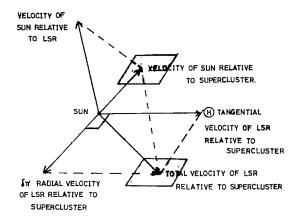

$$K-C=102(\pm 12) \text{ km sec}^{-1} \text{ Mparsec}^{-1}$$

If the tangential velocity Θ is independent of azimuth θ (as it would be if the supercluster has circular symmetry about Virgo), then the tangential expansion rate should be equal to our actual expansion rate away from Virgo. This is indeed the case because, as we have just seen, this latter expansion rate is close to the expansion rate for very distant galaxies of 100 km sec⁻¹ Mparsec⁻¹.

Peculiar Velocity of the Sun

When our results come to be compared with future observations, it will be convenient to work in terms of the peculiar velocity of the local standard of rest as defined here. In the supercluster reference frame, this peculiar velocity is the sum of the rotational velocity of the local standard of rest around the Virgo cluster. some 220 to 460 km/sec towards $l_{\rm H}=319^{\circ}$, $b_{\rm H}=-14^{\circ}$, and the peculiar velocity of the local standard of rest towards Virgo, some -200 to +200 km/sec towards $l_{\rm II} = 287^{\circ}$, $b_{\rm II} = 72^{\circ}$. Although the magnitudes of these velocities are not well determined, their directions are, and so the net peculiar velocity lies in a well defined plane. The limits on the velocities restrict the direction of the net peculiar velocity to a rectangle in this plane which is shown in Fig. 4. Referred to new galactic co-ordinates. the direction of the peculiar velocity of the local standard of rest relative to the supercluster reference frame should lie on the minor arc of the great circle between $l_{\rm II}=312^{\circ}$.

 $b_{\rm H}=27^{\circ}$, and $l_{\rm H}=331^{\circ}$, $b_{\rm H}=-56^{\circ}$. If Mach's principle, were true, it would be expected that this "local" inertial frame of the supercluster would be non-rotating with respect to distant matter. It will be possible to check this when more information is available about the possible anisotropy of the microwave

•VIRGO

Fig. 4. The components of the peculiar velocity of the Sun relative to the supercluster. The shaded areas represent the range of directions within which the total peculiar velocities should lie.

background. Knowledge of the amplitude and phase of the anisotropy component with a 24 h period would determine the peculiar velocity of the Sun with respect to the very distant matter which last scattered the radia tion. To make the comparison we must subtract from this velocity the solar motion with respect to the local standard of rest, which is caused by the rotation of the Galaxy, and its peculiar motion relative to the Local Group^{18,19}. Then we obtain the peculiar velocity of the local standard of rest with respect to distant matter, which can be compared with our estimate of the peculiar velocity with respect to the supercluster. If our estimate is correct the difference between the two should give the velocity of the supercluster with respect to distant matter (see Fig. 4). In view of the measurements of Partridge and Wilkinson³, the component of this velocity along $\delta = -8^{\circ}$ cannot exceed a few hundred km/sec. If in fact future observations show that the peculiar velocity of the local standard of rest is in reasonable accord with our estimate, then this would tend to confirm Mach's principle, that local inertial frames are non-rotating with respect to distant matter, to an accuracy of 10 3 sec of are/century, a 500-fold increase over the present precision of the comparison*.

Finally, we may note that if this picture of the super cluster turns out to be in accord with the observations. it would help to explain the curious result noted by Sandage²⁰ and de Vaucouleurs²¹ that the Hubble constant derived from galaxies in the northern galactic hemisphere is about 25 per cent less than that observed in the south. using the same distance scale. The galaxies in the north lie in our supercluster and partake in its peculiar contraction, so that the measured Hubble constant will be less than its true value. In the south, nearly all the galaxies used lie in the nearby supercluster, the edge of which can be seen in Fig. 2. They are spread roughly symmetrically about the line joining the Galaxy to Virgo. and so on average the rotation of the nearby supercluster will have no net effect on the radial velocities of these galaxies. Because these galaxies partake in the peculiar contraction of their own supercluster, the measured Hubble constant for them will be larger than the true value. A rough calculation shows that this effect is of the right general order of magnitude.

Conclusions

Future observations of the 24 h anisotropy of the cosmic microwave background are expected to reveal our peculiar velocity with respect to distant matter. Although part of this velocity is caused by our rotation in the Galaxy. our discussion shows that a significant contribution could arise from our motion in the local supercluster. Numerical estimates of the magnitude of this motion are rather uncertain at present, partly because of the scatter in the data and partly because there are so few observed radial velocities and distances of galaxies in the southern hemisphere. The direction of this motion, however, is hemisphere. better determined, and when it can be compared with the direction of our observed peculiar velocity with respect to distant matter we should be able to derive important information concerning the nature of the local supercluster and the validity of Mach's principle.
We thank Professor G. de Vaucouleurs for a helpful

We thank Professor G. de Vaucouleurs for a helpful discussion on the analysis, and Dr M. J. Rees for his many comments and criticisms of the theory.

Spectrum of the 3° K Cosmic Microwave Radiation

T. F. HOWELL J. R. SHAKESHAFT

Mullard Radio Astronomy Observatory, Cavendish Laboratory University of Cambridge

Measurements of the 3° K cosmic blackbody radiation at frequencies below about I GHz have a limited accuracy because radiation from the Galaxy becomes a dominant component. Measurements at 408 MHz and 610 MHz nevertheless show that there is a radiation component at these frequencies which is consistent with a blackbody spectrum of about 3° K.

MEASUREMENTS of the intensity of the cosmic microwave radiation have already been made over the range of frequency 1.407 GHz to 36.6 GHz (refs. 1-7) and all are consistent with this radiation having a blackbody spectrum corresponding to a temperature between 2.5° K and 3.0° K. The work of Scheuers and Weymanns, however, has shown that at lower frequencies deviations from this blackbody spectrum may perhaps be expected because of the presence of free-free radiation from intergalactic gas, the precise nature of the deviations depending on the density and thermal history of the gas. In view of the importance of further information on these matters, an attempt has been made to determine the spectrum at the frequencies of 408 MHz and 610 MHz, even though the accuracy attainable at frequencies below 1 GHz is limited by the fact that radiation from the Galaxy is the dominant component.

The experimental method has been described previously3. It relies on a measurement of the difference of noise output from an antenna and from a reference termination immersed in liquid helium. The antennas used were optimal horns with E-plane slant heights of 6 \(\lambda \), which provided beam-widths of 15°. The scaled dimensions lead to identical reception patterns, thus simplifying the comparison of the antenna temperatures at each frequency. The horns were oriented with their E-planes along the meridian.

Table 1 gives a summary of the measured antenna temperatures for the celestial North Pole and the corrections necessary to derive the effective sky temperatures. The passage of the galactic plane through the side-lobes of

	Table 1	
	408 MHz	610 MHz
Excess temperature, antenna	21·0 ± 0·7° K	7·85 ± 0·5° K
over load Load temperature	5·6±0·2° K 1·3±0·1° K	5·7 ±0·2° K 1·95 ± 0·1° K
Atmospheric emission Ground contribution Contribution from loss in horn	0·6±0·4° K 0·4±0·2° K	0·8 ± 0·4° K 0·4 ± 0·2° K
Corrected pole temperature	$24.3 \pm 0.9^{\circ} \text{ K (r.m.s.)}$	10.4 ± 0.7° K (r.m.s.)

the reception patterns caused diurnal variations of the antenna temperatures and the values quoted correspond to the minima in these variations which occurred when points at right ascension 06h and 18h were in transit. No attempt has been made here to allow for the variations of sky temperature over the antenna beams so that the 408 MHz value should not be compared directly with that. measured earlier at 404 MHz (ref. 10).

Because there now seems to be good agreement between experimental and theoretical values of the atmospheric emission11, the brightness temperatures quoted by Hogg12 have been used with an assumed error of ±0.1° K to allow for variations in meteorological conditions during the observations.

Ground radiation was reduced as much as possible by shielding the antennas with a wire mesh screen underneath them, lifted at the edges to obscure the horizon from the mouth of each horn. The residual contributions were calculated using the measured reception pattern, the theoretical transmission coefficient of the mesh and the effective values of ground temperature found by Pauliny-Toth and Shakeshaft¹⁰ at 404 MHz. These calculations: were checked experimentally by measurements with a scaled 1.407 GHz horn which could be screened so

thoroughly that the ground contribution was negligible.

In order to detect the presence of a radiation component with a spectrum different from that of the galactic radiation, the contribution of the latter and also of the integrated emission from discrete radio sources must be estimated. In view of uncertainty concerning the precise value of the spectral index of the galactic radiation in this frequency range some additional measurements were undertaken to determine this more precisely. These consisted of drift scans with the horns directed at various declinations and connected to Dicke-type receivers. Matched terminations in liquid nitrogen were used as reference sources. The temperatures measured at the two frequencies were then plotted against each other in the manner described by Turtle et al.¹³ to obtain the differential spectral index β , defined as $\Delta T \propto v^{-\beta}$, characterizing the galactic radiation. Omitting regions of low galactic latitude where thermal radiation from H II might be significant, the value of β was found to be 2.8 ± 0.1 between 408 and 610 MHz. This, incidentally, provides valuable confirmation of the previously reported¹³⁻¹⁵ steepening of the galactic spectrum above 178 MHz.

The mean (temperature) spectral index of bright radio sources is 2.72 ± 0.2 in this range and there is no evidence for any substantial deviation from this value for sources as weak as $S=4\times 10^{-28}$ Wm⁻² Hz⁻¹ at 408 MHz (G. G. Pooley, private communication). Down to this level the sources observed individually already contribute a large fraction of the whole 14 of the integrated source radiation. Although this component may show a slightly different spectrum from the brighter sources themselves, because of red-shift effects, it is so much less14 than the galactic contribution that the combined radiation from the galaxy and discrete sources must have a spectral index also close to 2.8 ± 0.1 . When this value is compared with β corresponding to the ratio of the two corrected pole temperatures in Table 1, that is, $2 \cdot 1 \pm 0 \cdot 2$, it is immediately clear that there is an extra component of radiation characterized by a much lower spectral index. The analysis may be continued as follows.

Suppose that this latter component has a blackbody spectrum (that is, $\beta = 0$). Then, writing T_e for the brightness temperature of the extra component and T_g for the combined galactic and discrete source brightness temperatures at 610 MHz, we have

$$T_e+T_g=T_{610}$$
 $T_e+nT_g=T_{408}$ where $\log n=\beta\log{(610/408)}$ so that $T_e=rac{1}{n-1}\left(nT_{610}-T_{408}
ight)$

For $\beta = 2.8 \pm 0.1, n = 3.08 \pm 0.10$

 $T_e = (3.7 \pm 1.2)^\circ \text{ K (root mean square error)}$ and

No correction has been made for any linear polarization of the radiation because the maps published by Berkhuijsen et al.17 show that (a) the polarized component smoothed by a 15° beam will be very small, (b) the polarization vectors have similar directions at the two frequencies, and (c) the spectral index of the polarized component is close to 2.8.

The results are illustrated in Fig. 1, which shows the spectrum of the radio background radiation in the frequency range 100 MHz to 100 GHz (refs. 1-7 and 18). The temperatures reported in this paper are plotted (as the equivalent brightnesses) together with the extra component T_e derived here. It can be seen that the magnitude of the extra component is consistent, within the limits of error, with a blackbody spectrum of about 3° K extending from 36.6 GHz to 408 MHz, a frequency range of 90:1. If the excitation of interstellar cyanogen molecules at 115 GHz can also be attributed to this radiation component19, as now seems very probable20, the range of frequency consistent with a blackbody spectrum is 280:1. This creates severe difficulties in attempts^{21,22} to explain the excess radiation in terms of the thermalization of starlight by means of interstellar dust grains.

Taking account of the quoted error, an upper limit of about 2° K may be set on any contribution from the intergalactic gas at 408 MHz. On the assumption of a present cosmological density of 2×10^{-5} particles/cm³, this implies that the epoch of any heating process causing ionization of the intergalactic gas was more recent than that corresponding to a red-shift z=200. Other arguments

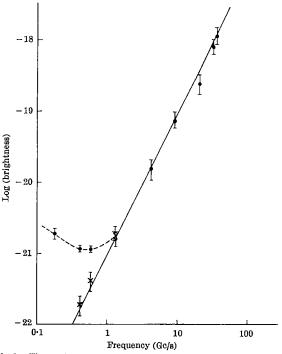

Fig. 1. The spectrum of the radio background radiation in the frequency range 100 MHz to 100 GHz. The units of brightness are Wm⁻¹ Hz⁻¹ steradian⁻¹. The crosses indicate the excess component reported in the present paper. The solid line corresponds to a temperature of 3° K and the dashed line to the total background at the celestial North Pole.

(for example, refs. 23-26) in fact suggest that this epoch was more recent, corresponding to a value of z between 2.5 and 30. The upper limit set by the new observations does not therefore press closely on these estimates. In principle the expected deviations from a blackbody spectrum are greater at still lower frequencies, but in view of the relatively more intense galactic radiation it is doubtful whether further efforts to detect them are worthwhile.

Interhemispheric Transfer of Debris from Nuclear Explosions using a Simple Atmospheric Model

bу

D. H. PEIRSON R. S. CAMBRAY

Atomic Energy Research Establishment, Harwell, Berkshire Using a simple atmospheric model, expressions for the reservoirs of fission products in the atmosphere from the 1961–62 nuclear explosions are found. Estimates of the rate of interhemispheric transfer and the ratio of northern and southern reservoirs are computed from observed values of the fission products.

During the series of nuclear explosions made by the USA and USSR in 1961–62, massive amounts of radioactive fission products were injected into the atmosphere¹. The portion of this nuclear debris inserted directly into the troposphere was removed within a few months, chiefly by rain. The remainder inserted above the tropopause will have undergone more prolonged mixing and redistribution under the influence of atmospheric motions and gravitation, before passing into the troposphere and falling out as before.

The amount and distribution of fission products within the stratosphere have been observed directly by sampling devices attached to aircraft² and balloons³. Indirectly, it is possible to observe the stratospheric behaviour of this debris by studying the concentration of fission products in tropospheric air and the deposition on the Earth's surface.

By using a simple model of the atmosphere it is possible to derive expressions for the reservoirs of fission products of the northern and southern hemispheres as functions of the gross rate of exchange between hemispheres and the fall-out rate. When observed values (1963–66) of the ratio of cerium-144 to caesium-137, in ground level air, are inserted into the theoretical expressions, approximate estimates can be made of the rate of interhemispheric transfer and the ratio of northern and southern reservoirs at any time. Similar estimates may be derived from direct observations of the stratospheric reservoir⁴ and global deposition^{5,8}.

A conventional meteorological approach might lead to dividing the atmosphere into layers, denoting the troposphere, the stratosphere and even the mesosphere. followed by further vertical sub-divisions, north and south of the equator. It is doubtful whether the observations available for the present computation have the necessary precision and extent to provide the parameters Instead, it is for these four or more compartments. simpler and more realistic to separate the atmosphere into northern and southern hemispheres, that is into two compartments separated by a vertical extension of the equator. This separation may be justified by the ability of the hemispheres temporarily to preserve separate identities, for example, by the preferential deposition in the same hemisphere of debris injected into the northern stratosphere. Furthermore, such debris, when observed in the troposphere for months after injection, is uniformly mixed in age or quality within the hemisphere, as shown by the fission product ratios7,8, with a sharp demarcation at or about the equator.

The proposed model (Fig. 1) consists of northern and southern compartments with reservoirs x and y, which have a fractional gross rate of exchange, K (year⁻¹). Again for simplicity the fractional rate of deposition, k (year⁻¹), is taken to be equal for both hemispheres. although there is no direct evidence available to support

the assumption of symmetry. The rate of change of each reservoir is therefore given by the gain from the other hemisphere less the loss to the other hemisphere and the losses by radioactive decay and by deposition.

$$\frac{\mathrm{d}x}{\mathrm{d}t} = Ky - Kx - \lambda x - kx$$

$$= Ky - x(K + \lambda + k)$$
Similarly,
$$\frac{\mathrm{d}y}{\mathrm{d}t} = Kx - y(K + \lambda + k)$$

where λ is the constant of radioactive disintegration for a particular fission product. The solutions of these simultaneous equations are

$$x = \frac{e^{-(k+\lambda)t}}{2} \left[x_0(1 + e^{-2Kt}) + y_0(1 - e^{-2Kt}) \right]$$
 (1)

$$y = \frac{e^{-(k+\lambda)t}}{2} \left[x_0 (1 - e^{-2Kt}) + y_0 (1 + e^{-2Kt}) \right]$$
 (2)

where $x = x_0$ and $y = y_0$ when t = 0, and by addition $x + y = (x_0 + y_0) e^{-(k+\lambda)t}$ as expected. Let x and y be taken as measures of a long-lived fission

Let x and y be taken as measures of a long-lived fission product such as caesium-137 (half-life 30 years) in the northern and southern hemispheres, respectively; let X_0 and Y_0 be introduced as the ratios, at t=0, of cerium-144 (285 days) to caesium-137 in the respective hemispheres. Then, assuming no fractionation, the ratio of cerium-144 to caesium-137 in the northern hemisphere at time t is given, from equation (1), by

$$X = \frac{X_0 x_0 (1 + e^{-2Kt}) + Y_0 y_0 (1 - e^{-2Kt})}{x_0 (1 + e^{-2Kt}) + y_0 (1 - e^{-2Kt})} \cdot e^{-\lambda' t}$$

$$= \frac{X_0 r_0 + Y_0 \tanh Kt}{r_0 + \tanh Kt} \cdot e^{-\lambda' t}$$
(3)

which is independent of k the deposition rate and where

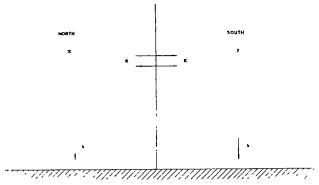

Fig. 1. The atmospheric model.

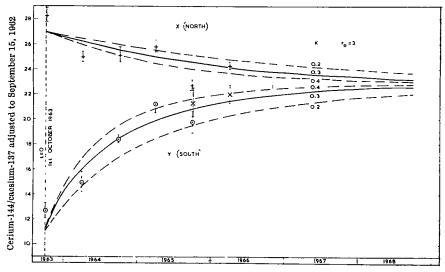

Fig. 2. Variation of the ratio of cerium-144 to caesium-137, 1963-66, in surface air. +, Northern stations (refs. 9-11); O, southern stations (refs. 12-14); ×, Pretoria and Aspendale (ref. 11).

$$r_0=x_0/y_0$$
, $\tanh Kt=rac{1\,-\,{
m e}^{-2Kt}}{1\,+\,{
m e}^{-2Kt}}$ and λ' is the difference

between the disintegration constants of cerium-144 and caesium-137.

Similarly, the ratio in the southern hemisphere is given, from equation (2), by

$$Y = \frac{X_0 r_0 \tanh \frac{Kt}{r_0 \tanh \frac{Kt}{Kt} + \frac{Y_0}{1}} \cdot e^{-\lambda' t}}{r_0 \tanh \frac{Kt}{Kt} + \frac{Y_0}{1}} \cdot e^{-\lambda' t}$$
(4)

Measured values of the ratio of cerium-144 to caesium-137 will be compared with these expressions for X and Y in order to extract estimates of K, the rate of interhemispheric transfer, and r_0 , the ratio of reservoirs at t=0.

In Fig. 2, equations (3) and (4) are drawn for selected values of K and r_0 . Average values of the ratio of cerium-144 to caesium-137 observed in surface air have been inserted for the northern and southern hemispheres. This implies that the ratio measured near the ground is representative of the whole hemisphere, which is assumed to be well mixed, at least as observed from the Earth's surface. The theoretical curves and experimental results have been adjusted to remove the effect of radioactive decay. The period of comparison was chosen to start in the second half of 1963 to allow time for the removal of the direct injection into the lower stratosphere of the debris from the 1962 explosions. The experimental data represent six-monthly averages from six stations in the northern hemisphere or from four stations in the southern hemisphere; the former are derived from a series of British reports by Cambray et al. 9-11, and the latter from the American Health and Safety Laboratory series 12-14, after adjustment by 6 per cent to normalize the two sets of data. The comparison for the southern hemisphere has been extended by the inclusion of data for Pretoria and Aspendale¹¹. No stations lying within the latitude range 25° N. to 25° S. were chosen because of the low values of radioactivity in this region and because of seasonal effects in the troposphere associated with movement of the solar equator. As a further restriction on choice of data, monthly results, which were likely to be affected by tropospheric debris from the small Chinese and French explosions since 1963, were rejected. Such interference was trivial until about mid-1966 when it became more general; sufficient to interrupt the approach to equilibrium between the two hemispheres $(X = Y \text{ as } t \to \infty)$ shown by the family of curves in Fig. 2.

The comparison of experimental results and theory in Fig. 2 makes it possible, within the limits imposed by the simple model, to account quantitatively for the interhemispheric exchange. Thus during the period 1963-66 the rate of exchange, K, lay in the range 0.2 to 0.4 year 1 and the ratio of the northern to southern reservoirs at October 1, 1963, r_0 , was in the range 2 to 4.

After subtraction and addition, equations (1) and (2) may be written

$$x - y = (x_0 - y_0)e^{-(k+\lambda+2K)t}$$

$$x + y = (x_0 + y_0)e^{-(k+\lambda)t}$$
and
$$\frac{x - y}{x + y} = \frac{x_0 - y_0}{x_0 + y_0} \cdot e^{-2Kt}$$

$$= \frac{r_0 - 1}{r_0 + 1} \cdot e^{-2Kt}$$
(6)

This treatment using differences follows a suggestion by Machta in a private communication. In Fig. 3, equations (5) and (6) are fitted in log-linear form to the determinations of the reservoirs x and y in terms of megacuries of strontium-90. Values for x and y were obtained by Feely (ref. 4 and in a private communication) at various times by integration of the concentrations of strontium-90 observed from aircraft up to about 22 km and from balloons up to about 35 km. Values for the rate of interhemispheric exchange, K, and the ratio of reservoirs at t=0, r_0 , may be simply derived from the slope and intercept of equation (6). In addition equation (5) provides estimates of the rate of deposition, k, and, using r_0 , the northern and southern reservoirs at t=0, x_0 and y_0 .

Table 1. SUMMARY OF RATE AND RESERVOIR ESTIMATES (1968-66)

Method	Interhemispheric transfer rate K (year-1)	Ratio of reservoirs at Oct. 1, 1963 r_0	Deposition rate k (year-1)	Reservoirs: MC Total $x_0 + y_0$	'i of strontium-90 North	at Oct. 1, 196; South

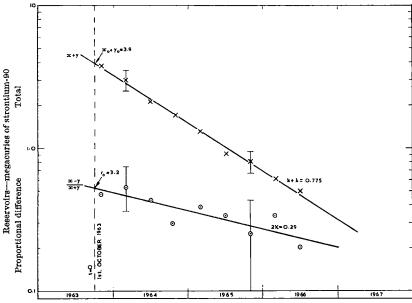

Fig. 3. Strontium-90 in the stratospheric reservoirs, 1963-66. Derived from Feely et al. (ref. 4 and private communication).

The deposition in each hemisphere of a fission product such as strontium-90 is given respectively by kx and ky. The total deposition

$$k(x + y) = k(x_0 + y_0)e^{-(k+\lambda)t}$$
(7)

and the proportional difference is given by equation (6) as before.

Two estimates of the annual global deposition of strontium-90 are available, based on sampling over networks of stations established by the $UK^{6,11}$ and the USA. The British results are usually 20 per cent higher. That the American, probably because of differences in sampling and in the method of integration over the Earth's surface. Equations (7) and (6) are fitted in Fig. 4 to the British results. Estimates of K, r_0 and the other parameters can be extracted as from the reservoir data. The same treatment of the deposition measured by the American network provides alternative estimates for these quantities.

The estimates of the various parameters extracted from

the preceding computations are summarized in Table 1. The uncertainties quoted in the table refer to standard errors derived from the curve fitting by least mean squares. No weight has been attached to the errors ascribed to the observations (Figs. 3 and 4); these are possibly nominal rather than actual and in some cases demonstrably pessimistic. It is clear that in the cases of the method of global deposition, the strain of fitting to only three points (Fig. 4) is shown by the meaningless values for y_0 and r_0 . On the other hand, the standard deviations, associated with the estimates by the global deposition method, of k and $x_0 + y_0$ are probably too small.

The values obtained for K, the rate of interhemispheric transfer, are probably in reasonable agreement. If the value obtained by the stratospheric reservoir method is significantly low, then it implies that this reservoir is shielded from faster transfer rates outside the stratosphere. These faster rates could apply above in the

mesosphere as computed by Murgatroyd and Singletonie, or below in the upper troposphere as calculated by Nydal¹⁷ for carbon-14. There is no evidence, however, that a sufficient proportion of the total debris resides for long enough in these other regions. The range of values for K given by the first two methods listed in Table 1 suggests that the mean residence time (1/K) against interhemispheric transfer lies in the range three to five years. This refers to the gross interhemispheric transfer, but it is the same as the value derived by Nydal¹⁷ for the exchange of gaseous carbon-14 between northern and southern stratospheres. Strictly, K is not a true atmospheric parameter because it is calculated from the behaviour of particulate debris: Feely² has shown that there is some separation of particulate and gaseous debris.

The estimates of r_0 obtained by the first two methods are mutually consistent at a value of 3 on October 1, 1963. The ratio of reservoirs at later times may be obtained from the ratio

of equations (1) and (2), namely,

$$r = \frac{x}{y} = \frac{r_0 + \tanh Kt}{r_0 \tanh Kt + 1}$$

The average value for the deposition rate corresponds to a mean residence time (1/k) of 16 months, which, of course, agrees with Feely's determination using his own results. There is no indication from these results and from the less precise global deposition of an increase with time, during 1963–66, of the apparent residence time.

Superficially, the estimates obtained for the total reservoir $x_0 + y_0$ have reasonable precision and apparently the estimate (4.7) by American deposition is consistent with the other two, but the British estimate (5.4) by deposition is significantly larger than that (3.9) by the stratospheric reservoir method. In fact, such is the vastness of the extrapolation required from small samples to the global scale, in each of the three methods, that systematic errors probably outweigh the random uncer-

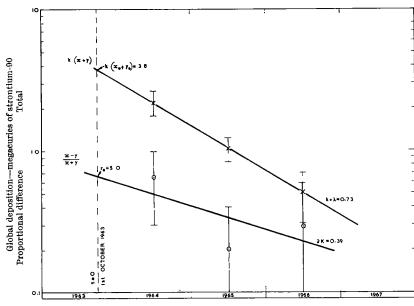

Fig. 4. Global deposition of strontium-90, 1964-66. Derived from Cambray et al. (ref. 5).

tainties and the agreement is surprisingly good. Any tendency to overestimate by the deposition method implies that there is no undetected enhancement18 of deposition on the sea compared with the measured deposition on land.

Quantitative Studies with Antilymphocytic Antibody

bу M. F. A. WOODRUFF B. L. REID K. JAMES

Department of Surgical Science, University of Edinburgh, MRC Research Group on Experimental and Clinical Problems of Transplantation Radioactive labelling has been used in measuring the amount of IgG taken up from antilymphocytic serum by lymphocytes, and the proportion of antilymphocytic IgG in various preparations of this immunoglobulin.

LYMPHOCYTES exposed in vitro to specific antilymphocytic serum (ALS) become coated with antibody^{1,2}. In the absence of complement, ALS agglutinates lymphocytes³⁻⁵ and in appropriate conditions of culture stimulates blast transformation⁶ and uptake of uridine and thymidine^{7,8}: in the presence of complement it causes lysis3,4

In experiments with horse-anti-human ALS based on measurements of uptake of tritiated uridine and thymidine by lymphocytes in vitro, it was found that most of the stimulating activity resides in the IgG component of the serum. It was further shown that when lymphocytes were exposed to ALS for short periods of time and then washed twice before being put up in culture, exposure for 15 min resulted in only very slight stimulation, whereas exposure for 60 min resulted in nearly maximal stimulation, as judged by subsequent uptake of tritiated uridine. We set out to extend this work in two ways.

In the first place, we have used radioactive labelling to determine the mean number of IgG molecules taken up when lymphocytes are incubated in vitro with IgG prepared from ALS (referred to hereafter as ALS IgG) and from normal serum.

Second, by combining radioactive studies with experiments in which the stimulating activity of various preparations of IgG is measured before and after absorption with standard numbers of lymphocytes, we have attempted to estimate the proportion (R) of antilymphocytic IgG in each preparation, that is, the proportion of IgG molecules which are antilymphocytic in the sense that they stimulate lymphocyte transformation.

Horse-anti-human ALS and IgG were prepared as described earlier. Samples of ALS IgG and normal IgG were labelled with iodine-131 by the method of Hunter and Greenwood¹⁰. Suspensions of lymphocytes were prepared and cultures were set up as described before⁸ except that, unless otherwise stated, the number of lymphocytes in a culture was 3×10^6 instead of 10^7 and the dose of tritiated uridine in a culture was 0.5 μc. The total volume of each culture was 3 ml. and the medium consisted of medium 199 with 25 per cent inactivated autologous plasma.

As a preliminary, dose response curves were established showing the uptake of tritiated uridine in cultures containing either iodine-131-labelled or unlabelled antilymphocytic IgG in amounts ranging from 0.25 to 2.0 mg per culture. Cultures containing tritiated uridine but no iodine-131 were treated as previously described. The cells were washed successively in phosphate buffered saline (three washes), 5 per cent trichloroacetic acid, phosphate buffered saline, and absolute methanol, and digested with the minimum possible quantity of hyamine hydrochloric acid. Scintillant was then added and counting was carried out with a Packard 'Tricarb' scintillometer. The ratio of the c.p.m. of cultures containing IgG preparations to the mean c.p.m. of control cultures without added Ig(; was calculated and is referred to in what follows as the relative count. Cells and supernatants from suspensions containing labelled IgG were counted for iodine-131 in a well-type scintillation spectrometer incorporating a 2 in. sodium iodide crystal (Nuclear Enterprises 'Gammamatic'). Cells from cultures which contained both iodine-131-IgG and tritiated uridine were prepared for liquid scintillation counting as described and counted on two channels, one adjusted for tritium and the other for iodine-131. counting known amounts of isotope it was found that for values of the external standard within the range accepted in the experiment, the efficiency of the tritium channel was 12.5 ± 1.6 per cent for tritium and 2.90 ± 0.17 per cent for iodine-131, and the efficiency of the iodine channel for iodine-131 was 74.7 ± 2.9 per cent. (This calibration was kindly undertaken by Dr John Simpson of the Department of Medical Physics, whose help we gratefully acknowledge.) In analysing the experimental results allowance was made for the influence of iodine-131 on the count in the tritium channel. As Fig. 1 shows, the labelled IgG was slightly less stimulating than the unlabelled material. but even

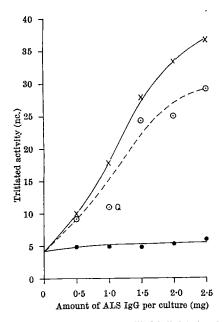

Fig. 1. Graphs showing the effect of ¹⁸¹I-labelled (\odot) and unlabelled (\times) ALS IgG, and of ¹⁸¹I-labelled normal horse IgG (\bigoplus), on the uptake of tritiated uridine by human blood lymphocytes in wiro. The point Q is an underestimate caused by quenching.

in the largest dose the difference was less than 20 per cent and it was considered that this could be neglected for the purposes of the investigation.

To determine the number of molecules of IgG taken up by each cell, lymphocytes suspended in culture medium were exposed to labelled IgG prepared from ALS. The cells were then spun down, separated from the supernatant, washed twice and counted, and an aliquot of supernatant was counted separately. Control tubes were set up with labelled normal IgG in place of IgG prepared from ALS. Assuming that all IgG molecules were labelled equally with iodine-131 and that the suspension contained no cells other than lymphocytes, the mean amount of IgG taken up by a cell (\hat{M}) in each tube is then given by

the equation $M = \frac{p G}{n}$, and the mean number of molecules

taken up per cell =
$$\frac{MN}{m} = \frac{pGN}{nm}$$

where
$$p = \frac{\text{Count of cells}}{\text{Count of cells} + \text{count of total supernatant}}$$

 $N = \text{Avogadro's number } (\text{$$\sim$} 6 \cdot 10^{23} \text{ molecules/mole}), G =$ amount of IgG per tube, n = number of lymphocytes pertube, m = molecular weight of IgG (=160,000). It clearly does not matter which units are used for G and M provided they are the same for both.

In practice, allowance must be made for the possible uptake of IgG by erythrocytes, which constituted 60-75 per cent of the total cells in the suspension. The proportion of erythrocytes could have been further reduced, but only at the cost of either greatly reducing the total yield of lymphocytes or by using procedures, such as agglutination of erythrocytes by an appropriate antiserum or lysis in a hypotonic solution, which we thought might modify the subsequent behaviour of the lymphocytes. The relatively high proportion of erythrocytes was therefore accepted and appropriate controls were set up to determine the uptake of IgG in the conditions of the experiment by erythrocytes alone. The amount of IgG taken up by the lymphocytes was then calculated on the assumption that the erythrocytes in the mixed population adsorbed as much IgG as the same number of erythrocytes in the absence of lymphocytes.

The protocol of one experiment is set out in Table 1, and the results of this and three other similar experiments are summarized in Table 2. The results obtained with cells from different donors differed appreciably, but the uptake of ALS IgG was always much greater than that of normal IgG in similar conditions of culture, the maximum observed values being 5.34×10^8 and 0.94×10^8 molecules per lymphocyte, respectively. The relationship of the mean uptake of ALS IgG and normal IgG to the amount present in the culture is shown in Fig. 2. The similarity of the curves relating to ALS IgG in this figure and Fig. 1 suggests that uridine uptake is linearly related to the number of IgG molecules taken up by a cell, and Fig. 3 shows that this is approximately true.

The ratio (R) of antilymphocytic to total IgG molecules in the preparation has been estimated by combining the results of studies of the uptake of ¹³¹I-IgG with absorption experiments based on stimulating activity as indicated by the uptake of tritiated uridine by lymphocytes in culture. In these experiments, a dose-response curve was first established in which the uptake of tritiated uridine by a fixed number of lymphocytes from a particular donor was plotted against the total amount of IgG added to the culture medium. The stimulating activity remaining after standard amounts of the same preparation had been absorbed for 1 h with a known number of lymphocytes from the same donor was then determined by using the absorbed material as a culture medium for fresh lymphocytes. Tritiated uridine was added to these cultures and the degree of stimulation was determined as usual. amount (E) of unabsorbed IgG per culture which would

This table shows the protocol of the first experiment.

Calculated on the assumption that the presence of lymphocytes has not affected the amount of IgG taken up by the erythrocytes.

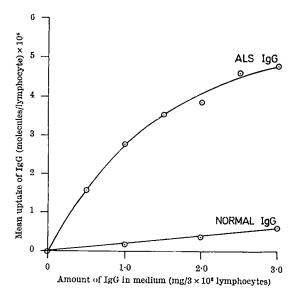

Fig. 2. Graphs showing the mean uptake of ¹³¹I-labelled ALS IgG and normal horse IgG by human lymphocytes against the amount of IgG added to each culture. The means have been calculated from the data shown in Table 2 after completing the table for the cells of each donor at each dose level by graphical extrapolation.

produce the same degree of stimulation was read from the dose-response curve. To allow for the possible effect of erythrocytes in the cell suspension, control tubes were set up to determine how much, if any, antilymphocytic activity was absorbed out in the conditions of the experiment by erythrocytes alone. The absorption due to lymphocytes alone was then calculated on the assumption that the erythrocytes in the mixed population absorbed out as much antilymphocytic activity as the same number of erythrocytes in the absence of lymphocytes.

To calculate R it is necessary to make some assumptions about the types of IgG molecule present in the preparation and their properties. The simplest set of assumptions is as follows. (a) The preparation contains only two classes of IgG molecule: antilymphocytic molecules which bind to lymphocytes and stimulate them to an equal extent (as measured by increase in uptake of tritiated uridine) and non-antilymphocytic molecules which neither bind nor stimulate. (b) The degree of stimulation produced in tests with a standard number of lymphocytes is a function of the number of antilymphocytic molecules in the preparation but independent of the number of non-antilymphocytic molecules. On this basis, using the symbols already

defined, the medium contained $\frac{G|N|}{m}$ molecules of IgG before absorption, of which $\frac{G|N|R}{m}$ were antilymphocytic and $\frac{G|N|(1-R)}{m}$ were non-antilymphocytic. After absorption the medium must have contained $\frac{E|N|R|}{m}$ antilymphocytic molecules to cause the observed uptake of tritiated uridine, so that the mean number of molecules taken up by a cell was $\frac{(G-E)NR}{n|m}$ (because, exclupations) only antilymphocytic molecules are taken up). Thus $\frac{M|N|}{m} = \frac{(G-E)NR}{n|m|} = \frac{p|N|G|}{n|m|} : R = \frac{M|n|}{(G-E)} - \frac{p|G|}{G|E|}$

Other possible assumptions on which the calculation of R might be based will be considered later in the light of the experimental results.

The protocol of a typical absorption experiment is set out in Table 3, and Table 4 summarizes the results of this and another similar experiment and shows the values obtained for R when these are combined with the measurements of uptake of ALS IgG labelled with iodine-131 contained in Table 2. As will be seen, these values, expressed as percentages, varied from 0.11 to 1.86.

Rather more precise values might have been obtained if it had been possible to use lymphocytes from the same donors in the absorption experiments and in the experiments on the uptake of labelled IgG. It is also possible that the allowance made for the presence of erythrocytes in the cell suspensions may have resulted in slightly too low a value of R because, contrary to the assumption which was made, the amount of IgG bound to erythrocytes may have been less when lymphocytes were present. An upper limit can be determined, however, by making no allowance at all for the presence of erythrocytes, and if this procedure is followed with the pair of experiments yielding the highest value of R the result is only 2.3 per

A more cogent criticism concerns the validity of the assumptions on which the calculation of R has been based. If these were true the values of R should be independent

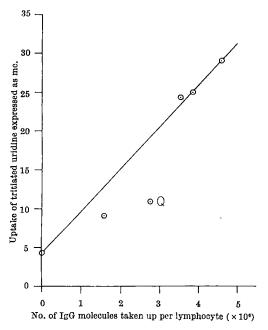

Fig. 3. Graph showing the approximately linear relationship between uptake of tritiated uridine and the number of IgG molecules taken up by a lymphocyte. The uptake of tritiated uridine denoted by the point Q is erroneously low because of marked quenching in the tubes on which this result is based.

of the amount of IgG (G) or the number of lymphocytes (n) used in the experiment. As Table 4 and Fig. 3 show, however, in experiments with cells from the same pair of donors, the values obtained for R are inversely proportional to G/n. The most likely explanation would seem to be that the ALS IgG used in the experiments, far from containing just two types of molecule as postulated, was much more heterogeneous. Such heterogeneity might take various forms, but the simplest hypothesis is that the antilymphocytic molecules are heterogeneous only in respect of their avidity, and that all IgG molecules which become attached to a lymphocyte exert an equal stimulating effect. Heterogeneity of this type may be defined in an operational way as implying simply that when ALS IgG is absorbed with lymphocytes the stimulating capacity of the absorbed solution is less than the stimulating capacity of a dilution of the unabsorbed solution containing the same total number of antilymphocytic IgG molecules, because the more avid molecules are preferentially absorbed whereas during dilution the population distribution remains the same.

It is easy to see that if such heterogeneity exists the experimental methods used would yield a value of R which was less than the true value*. It would seem to be premature to go further and attempt to develop a quantitative theory of the reaction until more experimental data are available with which the predictions of such a theory can be compared. It is worth noting, however, that the observed linear increase of R' with n/G, within the range of values which obtained in the experiment, suggests that even the highest observed value of R' may be a gross underestimate of R. Indeed, once the postulate of heterogeneity in respect of avidity is accepted it raises the possibility that R attains or comes very close to the theoretical limit of 1, because much, if not all, of what we have classed as non-antilymphocytic IgG might be antilymphocytic IgG of extremely low avidity. In this event

*Suppose a solution containing G grams of IgG, of which GR grams is made up of antilymphocytic molecules of varying degrees of avidity and G(1-R) grams is not antilymphocytic, is absorbed with n lymphocytes. Let Mn denote the amount of IgG absorbed, E the total IgG in a dilution of the original solution with the same stimulating effect in a standard test as

the absorbed material, and $R' = \frac{M n}{G - E}$ the experimental value obtained for R. Suppose further that in standard tests performed with dilutions of the original solution the degree of stimulation is f(x), where x is the total amount of IgG in a tube, and f(x) is a function which increases with x. After absorption the solution contains G - Mn grams of IgG, of which GR - Mn grams are antilymphocytic, and its stimulating effect is f(E). A dilution of the original solution containing the same number of antilymphocytic molecules

as the absorbed material would contain a total of $G-\frac{Mn}{R}$ grams of IgG-

and its stimulating capacity would be $f\left(G - \frac{Mn}{R}\right)$. Thus, ex hypothesi, $f\left(G-\frac{Mn}{R}\right) > f(E)$ and therefore because f(x) is an increasing function of

 $x, G - \frac{Mn}{R} > E$. Replacing Mn by R'(G-E), we have $G - \frac{R'}{R}(G-E) > 0$

 $E : G - E > \frac{R'}{R}(G - E) : R' < R.$

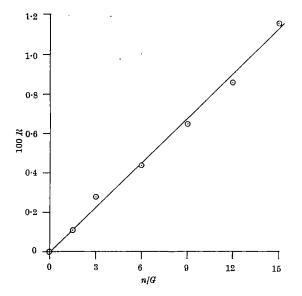

Fig. 4. Values obtained for R using the formula $R = \frac{M n}{(G - E)}$ in experiments with cells of donors II and V plotted against n/G. Symbols are explained in the text and Table 4.

R, as defined, would obviously not be a useful parameter for comparing different preparations of ALS IgG. The ideal would be to determine the distribution of avidity in the population of molecules making up each preparation, but useful comparisons could be made by determining R'for each for one or two values of G/n. This might be of some practical importance because it seems likely from

the results of these experiments that a great deal of the IgG in the preparation tested has at any rate very little stimulating effect on lymphocytes in vitro. This is scarcely surprising, for the horse in which the ALS was raised cannot be expected to have lacked previous immunological experience. It is not yet known whether there is a positive correlation between the immunosuppressive activity of ALS in vivo and its lymphocytestimulating activity in vitro; if there is, however, it would follow that even a highly purified preparation of ALS IgG, such as the one used in these experiments, contains a great deal of protein which is of no value as far as immunosuppression is concerned. It is conceivable that preparations containing a higher proportion of "useful" IgG might be obtained by raising sera in animals whose plasma concentration of IgG before immunization was either naturally low or had been reduced by plasmaphoresis. Alternatively, the same end might perhaps be achieved by modifying the schedule of immunization.

Conversion of Angiotensin I to Angiotensin II

K. K. F. NG J. R. VANE

Department of Pharmacology, Institute of Basic Medical Sciences, Royal College of Surgeons of England

Results obtained with the blood bathed organ technique indicate that angiotensin I is converted rapidly to angiotensin II in the pulmonary circulation and not by an enzyme in the blood.

When the enzyme renin is secreted into the bloodstream, it acts on a protein substrate in the plasma to release the decapeptide angiotensin I (ref. 1). This decapeptide is then converted to the octapeptide angiotensin II (ref. 2) which is physiologically much more active. The reninangiotensin system therefore requires two enzyme steps between the initial secretory process and the formation of the active circulating hormone. The biochemistry of the first enzyme, renin, has been investigated extensively3, but little is known about the second or "converting" enzyme. Work in vitro has shown that blood contains converting enzyme activity4, as do homogenates of heart. liver, aorta and ileum⁵.

Although angiotensin I has only 5-10 per cent of the activity of angiotensin II on smooth muscle 6-8, when injected intravenously into animals it causes a rapid rise in blood pressure scarcely distinguishable in height and time course from that produced by angiotensin II. The similarity of the responses has led to the assumption that, in vivo, the conversion of angiotensin I to angiotensin II takes place rapidly in the blood3. We have investigated

the in vivo conversion by means of the blood-bathed organ technique, and have found a time course which suggests that blood plays little or no part but that the conversion takes place rapidly in the pulmonary circulation.

The assay tissues were a rat stomach strip¹⁰ and two rat colonsii; these were suspended in polypropylene chambers and superfused12 in series with Krebs solution while the dog was being prepared. Their movements were recorded either on a kymograph by auxotonic levers13 of 16: I magnification or on a Beckmann-Offner dynograph with Ether strain gauges attached to the auxotonic levers. The initial load on the tissues was 1-3 g. All three organs were contracted by the angiotensins, the rat colon much more strongly than the rat stomach strip; the latter was included to detect catecholamines which, had they been released, would have caused relaxation. One of the rat colons was perfused intraluminally with propranolol (1 mg/ml. at 0·1 ml./min) to prevent relaxation by catecholamines which would interfere with the contraction induced by angiotensin.

Dogs of either sex weighing 10-30 kg were anaesthetized with halothane delivered from a Goldman vaporizer; anaesthesia was then maintained with chloralose (100 mg/kg, given intravenously) and supplemented when necessary with pentobarbitone (5-10 mg/kg, given either intramuscularly or intravenously). The trachea was cannulated and the lungs were ventilated mechanically. Polyethylene cannulae were tied into a femoral or carotid artery and a femoral or jugular vein for the removal and replacement of blood. Mean arterial blood pressure was recorded from a side-arm of the arterial cannula either on the kymograph with a mercury manometer or on the dynograph with a Statham P23Db transducer. In some experiments, a fine catheter was introduced through the left carotid artery until the pulse pressure recorded through it showed that it was in the left ventricle. It was then withdrawn until the change in pulse pressure showed that it was just above the aortic valves, in the ascending aorta. This catheter was used to make infusions directly into the total cardiac output.

Heparin (1,000 ru/kg) was injected intravenously and then the assay organs were superfused with arterial blood delivered by a constant output roller pump at a rate of 10 or 15 ml./min. The blood collected in a reservoir and was returned to the dog either by gravity or by a second channel in the roller pump. The assay system could be calibrated by infusions of angiotensin into the stream of blood after it had left the dog; thus an infusion of 15 ng/min into a flow of 15 ml./min would give an absolute change of concentration of angiotensin of 1 ng/ml. The assay system could also be calibrated by intravenous or intra-arterial injections into the dog, as described later.

The angiotensin I was that made from horse substrate by Dr L. T. Skeggs¹⁴, who sent us five ampoules each nominally containing 83·2 nmole or 108 µg. Ampoule No. 2 was broken on arrival, but the contents were extracted and 100 per cent recovery was assumed.

When superfused in Krebs solution, the rat colon preparations were contracted by angiotensin I. These contractions were bracketed between those produced by angiotensin II amide ('Hypertensin', Ciba) in order to assess the relative activities of the two peptides. Table 1 shows that in fifteen preparations the angiotensin I was 7-30 per cent as active as the angiotensin II (mean

Results are expressed as the relative activity of angiotensin I infusions (as the percentage activity of angiotensin II) on rat colons bathed in Krebs solution, in blood after incubation for the times shown, and after intra-aortic and intravenous infusions into the dog. All the rat colons were bathed in arterial blood, except those marked with an asterisk in dogs No. 9, 10 and 11, which were bathed in venous blood. A tracing from rat colon A in dog 4 is illustrated in Fig. 1, from B in dog 1 in Fig. 2, and from B in dog 8 in Fig. 3.

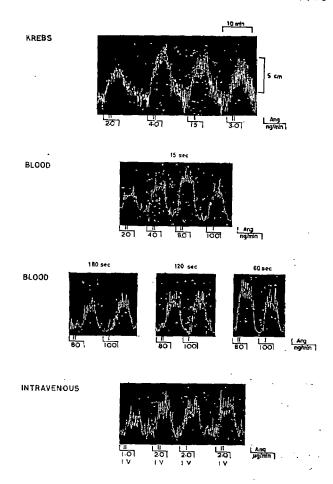

Fig. 1. A tracing from rat colon A in dog 4, showing comparisons of the activities of angiotensin I and angiotensin II on the rat colon bathed in Krebs solution, in blood after incubation for various times and after intravenous infusions. The peptides were given as infusion for 5 min periods. The relative activity of angiotensin I is: 23 per cent in Krebs solution; 33 per cent after incubation for 15 sec in blood, 110 per cent after 180 sec; 71 per cent after 20 sec; 38 per cent after 60 sec. After intravenous infusions, the relative activity is 110 per cent. Time, 10 min; vertical scale, 5 cm.

15 per cent, $S.E.\pm 2.0$). Table 1 also shows that the relative activity of the samples of angiotensin I varied from ampoule to ampoule, the third being particularly active.

An example of an assay in Krebs solution is shown in the top tracing of Fig. 1. The contraction caused by angiotensin I (15 ng/min) was intermediate between those produced by angiotensin II (3 and 4 ng/min). The decapeptide therefore had 23 per cent of the activity of the octapeptide.

The activity of the angiotensin I may have been a consequence of immediate conversion to angiotensin II within the assay organ itself, as suggested for other isolated organs on which angiotensin I acts. In our experiments, however, as in those of Gross and Turrian on the rat uterus, the slopes of the curves of dose against response for angiotensin I and angiotensin II were different, suggesting that both substances had inherent activity. It seems that the relative activity of angiotensin I to angiotensin II varies from one smooth muscle to another and that the variation is not connected with the presence of converting enzymes.

To measure the conversion of angiotensin I to angiotensin II in circulating blood, the assay organs were superfused with arterial blood from a dog, in some instances (Table 1) using the same rat colon preparations as in the experiments with Krebs solution. After the tissues had stabilized in blood, the relative activities of angiotensin I

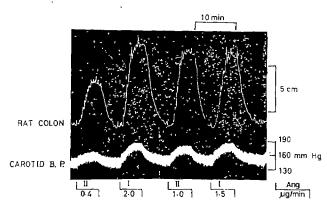

Fig. 2. A tracing from rat colon B in dog 1, showing a comparison of the effects of intravenous infusions of angiotensin I and angiotensin II on the contraction of the rat colon bathed in arterial blood and on the blood pressure response of the dog. Intravenous infusions of the angiotensins were made into the external jugular vein. The extent and time course of the contraction of the rat colon and of the rise in blood pressure after angiotensin I (1.5 μ g/min) were similar to those after angiotensin II (1.0 μ g/min). Time, 10 min; vertical scales, 5 cm and mm of mercury.

and II were compared again by infusing each substance into the blood on its way to the assay organs. This gave the relative activities of the two peptides after contact with blood for 15 sec. In order to assess the importance of the converting enzyme in blood, the contact time was increased by adding to the external circuit a piece of silicone tubing (3 mm internal diameter) lying in a water-bath at 37° C and sufficiently long to contain 45 ml. of blood. The blood which superfused the assay organs at a rate of 15 ml./min first passed through this incubating circuit. By making the infusions of angiotensin I and II at different points in the circuit, the peptides could be mixed with the blood for 60, 120 and 180 sec, before reaching the assay organs. Thus any conversion of angiotensin I to angiotensin II would have shown as an increase in the relative activity of the former. Table I shows that there was a slight increase in the relative activity of angiotensin I (27 per cent) after 15 sec contact with blood. a further increase to 40 per cent after 60 sec contact with blood and only after 180 sec contact was the relative activity increased to 93 per cent. If the relative activity of 15 per cent on the rat colon displayed by angiotensin I in Krebs solution represents 0 per cent conversion, whereas 100 per cent activity represents 100 per cent conversion to angiotensin II, the degree of conversion can be calculated (bottom line of Table 1). This calculation assumes that the activities of angiotensin I and II are simply additive and neither synergistic nor antagonistic. The interpretation of these incubation experiments is also complicated by the fact that angiotensin II is destroyed in dog's blood, with a half life of $\bar{120}$ sec (ref. 15). Thus, as well as possible generation of angiotensin II from angiotensin I, there was also inactivation. This was to some extent compensated for by making the matching infusions of angiotensin II into the incubating circuit so that they were in contact with the blood for the same time as the angiotensin I. Any error in this procedure would show as an over-estimate of the conversion.

A typical experiment is illustrated in Fig. 1, which shows the contractions of a rat colon preparation bathed in Krebs solution or in blood to various infusions of angiotensin I and angiotensin II. When the infusions were made so that they mixed with the blood for 15 sec before reaching the raticolon, there was little change in the relative activity of angiotensin I (23 per cent in Krebs, 33 per cent after 15 sec contact with blood). The next section of the figure shows the contractions when the infusions were made so that they mixed with the blood for 180 sec before reaching the rat colon. Angiotensin I now had about the same activity as angiotensin II, but it should be noted that the angiotensin II produced a much

smaller effect than after contact for 15 sec, indicating destruction in the blood. The next two sections show that as the incubation time was reduced the relative activity of angiotensin I became less. The last tracing shows the contractions of the rat colon after intravenous infusions of the two peptides when they were approximately equipotent.

It is therefore evident that the conversion of angiotensin I to angiotensin II is very slow in blood. The mean values (Table 1) show that there was only 14 per cent conversion after 15 sec contact, only 29 per cent after 60 sec, 62 per cent after 120 sec and 93 per cent after 180 sec. It can be concluded that in one circulation time (15–20 sec (ref. 16)) there is little or no conversion of angiotensin I to angiotensin II in the blood.

These results clearly contrast with those obtained after intravenous infusions of angiotensin I (Fig. 1) when 80 per cent is converted to angiotensin II (Table 1). Furthermore, the contractions of the rat colons show that the rate of conversion was rapid, for they occurred within the first minute of the infusion. Indeed, the time courses of the responses of the assay tissues and the blood pressure could not be distinguished from those after infusion of angiotensin II.

Figure 2 shows the results of another experiment in which the two peptides were compared for their effects on the blood pressure and on the blood-bathed rat colon preparation. The intravenous infusion of angiotensin I at a rate of $1.5 \,\mu\text{g/min}$ caused a rise in blood pressure and contraction of the rat colon similar to those caused by angiotensin II infused at a rate of $1 \,\mu\text{g/min}$. There was no detectable difference in the time courses of these effects.

These experiments confirm that, in vivo, angiotensin I is rapidly converted to angiotensin II (ref. 3). Where could such rapid conversion occur if not in the circulating blood? The assay organs were bathed in arterial blood so that angiotensin I infused intravenously traversed the pulmonary vascular bed before reaching them. This suggested that the conversion of angiotensin I to angiotensin II occurred during passage through the pulmonary circulation. The effects of intravenous infusions of angiotensin I on the rat colon bathed in femoral arterial blood were therefore compared with those induced by infusions into the ascending aorta, close to the left ventricle. The comparisons were made in five dogs (Table 1); all gave the same results, one of which is

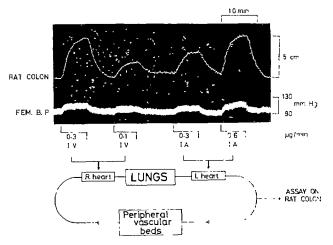

Fig. 3. A tracing from rat colon B in dog 8, showing an increase in the activity of angiotensin I on passage through the pulmonary circulation. Femoral arterial blood was superfused over the rat colon stop tracing) and blood pressure (bottom tracing) was measured from a side-arm of the arterial cannula. Infusions were made near to the right atrium (IV) or into the ascending aorta (IA). The responses show that intravenous infusions produced greater effects on the rat colon and on the blood pressure than did intra-arterial infusions. Twice the infusion rate (0-6 μ g/min) had to be given intra-aortically to match the effect of 0-3 μ g/min given intravenously. Time, 10 min; vertical scales, 5 cm and mm of mercury.

illustrated in Fig. 3. Intravenous infusions of angiotensin I (0·3 and 0·1 µg/min) gave graded contractions of the rat colon. To match the effects of the intravenous infusion of 0·3 µg/min, angiotensin I at twice the rate (0·6 µg/min) had to be given intra-arterially. Thus one circulation through the lungs was sufficient for substantial conversion of angiotensin I to angiotensin II.

The arterial infusions of angiotensin I resulted in a 30 per cent conversion to angiotensin II, as against an 80 per cent conversion after intravenous infusion (Table 1). Two deductions can be made from this observation; first, there must have been a loss of angiotensin I in the peripheral vascular beds after aortic infusion, for, had this not occurred, the angiotensin I would have re-circulated and given results identical to those of an intravenous infusion. Second, there could not have been a concomitant gain of angiotensin II activity, because any angiotensin II formed in the peripheral vascular beds would have passed through the pulmonary circulation without change¹⁵, thereby reaching the assay organs. Thus we can conclude that there was little or no conversion of angiotensin I to angiotensin II in the peripheral vascular beds, for the overall effect was a substantial loss of activity. From 50-70 per cent of infused angiotensin II disappears in the peripheral vascular beds¹⁵ and it is possible that angiotensin I disappears in the same way. The extent of conversion after intra-arterial infusions suggests that about one-third of the angiotensin I recirculates; if this is so, its loss in peripheral vascular beds is similar to that of angiotensin II.

All these results were obtained with angiotensin I prepared from the horse (ileu⁵ angiotensin I). Because the structure of dog angiotensin I is not known, it is possible

that endogenous angiotensin I is treated differently by the converting enzyme(s) of the dog. The following experiment was designed to test this possibility. Two banks of assay organs were used, one bathed in mixed venous blood obtained from a catheter in the right ventricle, and the other in arterial blood from a carotid Thus any conversion of angiotensin I to angiotensin II in the pulmonary circulation would have been detected as greater contractions of rat colons bathed in arterial blood than of those bathed in venous blood. Arterial blood was taken at a rate of 15 ml./min from a femoral artery into an incubating circuit of silicone tubing containing 75 ml. of blood maintained at 37° C. The blood was then infused into the femoral vein. Dog renin, partially purified by a method already described¹⁷, was infused at the rate of 12 U/min into the incubating circuit (Fig. 4) so that it mixed with the blood for 5 min before being pumped into the venous side of the circulation. It was hoped that, by using this technique, endogenous angiotensin I would be generated without substantially increasing the concentration of renin in the dog's circulation. The rat colons bathed in venous blood contracted much less (equivalent to less than 0.25 μg/ min of angiotensin II) than those bathed in arterial blood (equivalent to 0.5 μg/min of angiotensin II) (Fig. 4) showing that the contractor activity of the endogenous angiotensin had been greatly increased by passage through the pulmonary circulation. This experiment confirmed our supposition that dog angiotensin I, like horse angiotensin I, is converted to angiotensin II in the lungs. In a second experiment of the same design, in which venous blood

was used in the incubating circuit, results were similar.

Fig. 5 summarizes all results obtained with the horse angiotensin I and is based on the calculated conversion to angiotensin II in blood, after intra-aortic and intravenous infusions. In the 4–8 sec that it takes for blood to traverse the pulmonary circulation if, there was more conversion of angiotensin I to angiotensin II than after 120 sec in blood alone. Although it may not be valid to compare these in vivo experiments with the original estimation of the in vitro activity of converting enzyme in blood i, the rate of conversion was also found to be very slow, that is, 1·5 h for 50 per cent conversion and 6 h for 96 per cent conversion.

The conversion of angiotensin I to angiotensin II in the lungs may be caused by one or more of several possible mechanisms. First, the converting enzyme in blood may be sensitive to changes in oxygen or carbon dioxide tension. To test this possibility, the assay organs were bathed in mixed venous blood sampled continuously from the right atrium (three experiments) and the rate of conversion of angiotensin I to II was measured (Table 1). The relative activities of the two peptides after incubation for various times in venous blood were within the same

range as those found in arterial blood.

In the second possible mechanism of conversion of angiotensin I to angiotensin II, the converting enzyme circulating in the blood may be activated in some way by the enormous surface area of the pulmonary circulation. There is no evidence for such a mechanism. Third, the converting enzyme may be located on or in the pulmonary cells. This is the simplest and most attractive hypothesis and warrants further investigation.

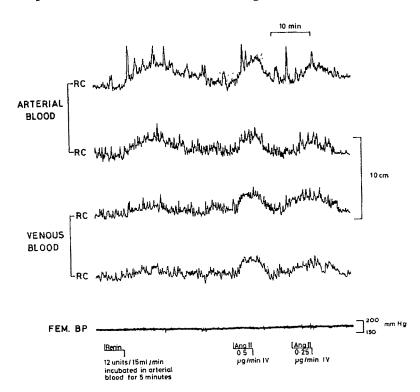

Fig. 4. Generation of angiotensin I by dog renin in blood and its subsequent conversion to angiotensin II by the pulmonary circulation. Arterial blood was taken from a femoral artery and pumped at the rate of 15 ml/min through an incubating circuit of 75 ml. and then into the femoral vein. Benin was infused into this incubating circuit at the rate of 12 v/min for 5 min. Two rat colons were bathed in carotid arterial blood (top two tracings) and two in mixed venous blood from the right ventricle (lower two tracings). Blood pressure (bottom) was recorded from a femoral artery. The activity of the polypeptide generated by renin was calibrated by making infusions of angiotensin II directly into the femoral vein. The rat colons bathed in venous blood showed that the activity on the venous side of the circulation was less than 0.25 \(\textit{\textit{m}} \) functions blood, however, showed an activity equal to that of 0.5 \(\textit{\textit{m}} \) in angiotensin II. Those bathed in arterial blood, however, showed an activity equal to that of 0.5 \(\textit{m} \) in angiotensin II. Showing that there was a big increase in activity after the peptide had crossed the pulmonary circulation. Time, 10 min; vertical scales, 10 cm and mm of mercury.

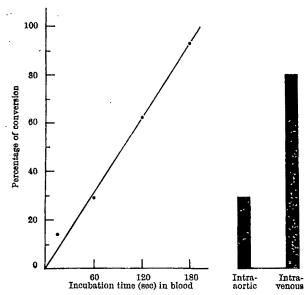

Fig. 5. Percentage conversion of angiotensin I to angiotensin II in blood, after intra-aortic and intravenous infusions. Fifty per cent conversion in blood requires at least 100 sec of incubation. The intra-arterial infusions showed 30 per cent conversion, whereas intravenous infusions, which only differed by the 4-8 sec passage through the pulmonary circulation, showed an 80 per cent conversion.

It seems therefore that the lungs are important in the metabolism of peptides, as well as of amines and prostaglandins¹⁸. Thus bradykinin but not eledoisin disappears in the pulmonary circulation¹⁸. The prostaglandins disappear almost completely²⁰, as does 5-hydroxytryptamine²¹; in contrast adrenaline, like angiotensin II, passes through without loss (unpublished results of Ginn and Vane). The fact that the pulmonary vascular bed acts as a selective filter for these substances, and its unique position in the circulation, makes it likely to be of equal, if not greater, importance to the liver in this respect.

Our results show that for the generation of circulating angiotensin II the lungs are the most important site. It is possible that other tissues can also generate angiotensin II locally but that this is destroyed before reaching the general circulation. Such local conversion is likely to take place after the blood has passed through the arterioles. Thus any angiotensin II formed locally in peripheral vascular beds will not constrict the pre-capillary resistance

We thank Dr L. T. Skeggs for angiotensin I, the MRC for a grant and P. Simpson and R. Adderley for technical assistance. One of us (K. K. F. N.) is an Overseas Scholar from the University of Singapore and thanks the members of the Blood Pressure Research Unit in Glasgow for teaching him their method for extraction of dog renin.

Bonding between Proteins and Lipids in the Envelopes of Halobacterium halobium

C. W. F. McCLARE Department of Biophysics, King's College, University of London

Simple experiments indicate that in the envelopes of Halobacterium halobium the lipids are bound to at least two types of proteins by different kinds of bond-polar and apolar. The polar bond may be an intermolecular chelate involving magnesium.

THERE is no convincing evidence at present in favour of any one membrane model1 although most discussions of the subject rightly stem from the ideas of Davson and Danielli, published some 30 years ago². It is clear, however, that, in proposing any model, the identification of bonds between the protein and lipid molecules of the membrane will be of critical importance, both in structure and function.

Because such bonds have not so far been specifically identified, the choice of an appropriate biological system for this investigation was important and eventually

focused on Halobacterium halobium. The high ionic strength within halophilic bacteria3, and of the medium in which they live4, imposes stringent requirements on these forces. It was argued, initially at least, that ionic forces within the Halobacterium membrane might be of lesser importance and apolar forces easier to recognize. Although the Davson-Danielli model implies that the bonds between the lipid bilayer and the proteins are polar, Green and Fleischer⁵ have shown that the "structural protein" isolated from mitochondria interacts hydrophobically with lipids. A similar interaction was expected

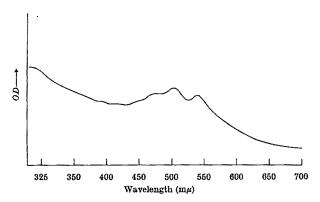

Fig. 1. Absorption spectrum, original preparation before dialysis.

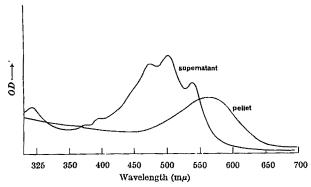

Fig. 2. Absorption spectra, orange supernatant and suspension of purple pellet.

here. Furthermore, the evidence of Christian and Waltho³ that the internal concentration of potassium is some one hundred times that of the medium suggested that the halophilic membranes might be an excellent transport system. Investigations by Brown⁵ had already shown (but see later) that the whole membrane dissolves in pure water to give lipoprotein complexes, and this indicated that the components might be easy to separate and characterize. When this work began we believed that Halobacterium halobium did not possess a cell wall⁵. As the work of Stoeckenius and Rowen⁵ has since shown, this is incorrect. Strictly speaking, the experiments to be described have been carried out on plasma membranes plus cell walls, which we will together denote by the term "envelope".

Experimental Techniques

 \dot{H} . halobium, strain NCMB 744 (which gave orange translucent colonies on agar slopes), was grown in 4 l. batches at 37° C with aeration and stirring in Sehgal and Gibbons medium⁴ at pH 6·5. Towards the end of the logarithmic growth phase (after 5–6 days) the cultures were removed and stored at 5° C or at -20° C until required. The bacteria were still viable and motile after storage for several months at -20° C.

Envelopes were prepared by the lysis method of Brown⁸ and stored, after purification, in basal salts solution (4 molar sodium chloride; 0.27 molar potassium chloride; 0.08 molar magnesium sulphate). After spinning for 2 h at 60,000g in a sucrose density gradient, in either basal salts solution or 0.02 molar magnesium chloride, the preparation gave a single maroon band at a density of 1.21 ± 0.01 g/ml. When viewed optically and in the electron microscope the preparation seemed homogeneous; on only a very small proportion of envelopes could any flagella be detected.

Two basic techniques have been used to separate the components of the envelope: (a) dialysis against pure water, which drastically reduces the ionic strength of the environment, and (b) extraction with chloroform—methanol solution, which would be expected to break hydrophobic bonds. We have preferred the simpler technique of Folch rather than the use of detergents which would also affect lipid—protein polar bonds.

The amino-acid analysis was carried out using a Beckmann 120B analyser. For the nitrogen determinations we used Kjeldahl's method and for the phosphorus determination we used Bartlett's method¹o. In the magnesium analysis, aliquots of the appropriate fractions were digested with AR perchloric acid (72 per cent) in borosilicate Kjeldahl tubes; the excess acid was evaporated in vacuo and the residues were dissolved in a solution of 0.4 per cent lanthanum chloride in 0.5 normal hydrochloric acid. Measurements were taken, using appropriate blanks and standards, with a Perkin-Elmer 303 or a Unicam SP90 atomic absorption spectrophotometer. The absorption spectra were determined with a Unicam SP800 recording spectrophotometer.

Dialysis Experiments

Envelopes were dialysed against changes of deionized water for 2 days and then centrifuged for 1 h at 17,000g. As a result an orange supernatant I_D and a purple pellet II_D were obtained. The purple pellet was resuspended in deionized water and respun until no further changes in the absorption spectrum could be detected. When viewed under a phase contrast microscope or in the electron microscope this product appeared as sheets of very low contrast. Absorption spectra of the original preparation, of the supernatant I_D and of a pellet suspension II_D were recorded and are shown in Figs. 1 and 2. The original preparation, as expected, shows considerable light scatter (Fig. 1). The amino-acid analyses of the two fractions I_D and Π_D are recorded diagrammatically in Figs. 3 and 4 (solid lines). In another experiment, the dialysate was returned to basal salts solution to test for reaggregation. After 2 days the product was spun for 2 h at 60,000g in a sucrose density gradient in basal salts solution; a diffuse orange upper band and a compact lower purple band were obtained, with no cross contamination.

Chloroform-Methanol Extraction

A thick suspension of envelopes (5 ml., about 4 mg N/ml.) in basal salts solution was shaken with chloroform methanol (50 ml.; 1:1 by volume. CM). The precipitated

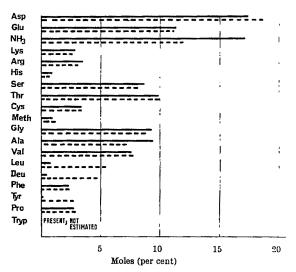

Fig. 3. Amino-acid analysis. —, Ib; ---, Icu.

salt and protein fraction, Icm, was spun down, washed with the solvent chloroform-methanol and amino-acid analyses obtained as before (Fig. 3, broken lines). combined supernatants and washings were evaporated to dryness on a boiling water bath, and re-extracted with chloroform-methanol, the resultant residue IIcm collected, and corresponding amino-acid analyses obtained (Fig. 4, broken lines).

Unlike fraction ID, which is a clear aqueous solution, fraction I_{CM} slowly gave a cloudy gelatinous suspension in water. This suspension immediately clarified on adding sodium dodecyl sulphate (SDS), and also emulsified

triolein and even paraffin.

The chloroform-methanol solution from an independent extraction was introduced under excess deionized water to remove methanol by diffusion, and left for 2 h. The resultant flocculus at the interface was separated by removal of upper and lower phases and subsequently washed with deionized water and chloroform. product was extracted with chloroform-methanol and the extract tested for lipids by paper-chromatography11. The protein residue from this extraction was also analysed, and agreed closely with IIcm here.

A protein-free lipid extract, in chloroform solution, was evaporated to dryness in vacuo in a rotating flask. An aliquot of a suspension of the purple fraction, containing a third as much phosphorus, was evaporated to dryness on top of this lipid at low temperature. The product was

soluble in chloroform-methanol.

Live bacteria were also extracted with chloroformmethanol, the precipitates discarded, the organic phase evaporated to dryness, extracted with chloroformmethanol and the residue analysed. The analysis again agreed closely with Π_{CM} .

Elemental Analyses

One envelope preparation was divided into aliquots for total analysis, for dialysis and for chloroform-methanol extraction. Each fraction (I_D , I_D , I_{CM} , I_{CM}) was prepared and analysed for nitrogen and phosphorus. Spectral correction was made for losses of ID and IID in washes. The results are given in Tables 1 and 2. The absence of the purple pellet fraction in the log-phase will be taken up later.

- * The results are expressed in molar ratios with phosphorus = 2. † Amino-acid analysis carried out on separate sample of $\Pi_{\mathbf{b}}$. ‡ Amino-acids expressed as moles per cent. Same preparation.

From these results the following principal points emerge. (a) Both dialysis and chloroform-methanol extraction each give rise to two fractions denoted as ID, IID and I_{CM} , H_{CM} . (b) The amino-acid compositions of I_D and Icm are closely similar. Each has an overall net negative charge as a result of a high proportion of acidic groups. (c) The amino-acid compositions of IID and IICM are very similar, but differ considerably from those of ID and ICM. (d) The greater part of the lipid (76 per cent of total phosphorus) is associated with ID in the dialysis experiments and with IIcm (100 per cent) in the chloroformmethanol experiments. (The lipids of H. halobium are negatively charged and highly hydrophilic11.)

The properties of I_D and I_{CM} are most readily explained if it is supposed that both in vivo and in In lipids are hydrophobically bound to an apolar part of these proteins which, after the lipids are removed by chloroformmethanol to give Icm, is unable to fold away from the water and consequently interacts strongly with sodium dodecyl sulphate. The other fractions IID and IICM were,

however, at first surprising.

The protein fraction IIcm, the residue obtained after evaporating the chloroform-methanol extract to dryness and re-extracting with chloroform-methanol, was insoluble in 8 molar urea, sodium dodecyl sulphate, water and acetic acid. The residue, however, was soluble in cresol from which it precipitated on the addition of chloroform—methanol. Because this protein was originally soluble in chloroform—methanol as a proteolipid complex, it is inferred that the lipids must have originally taken the protein into solution by bonds unaffected by a solvent (chloroform—methanol) designed to break hydrophobic interactions. It seemed possible therefore that in the proteolipid the lipids were attached to the protein by polar bonds. Yet after removing two-thirds of the lipid from the original extract in the process of isolating the proteolipid (Table 2), or after denaturation, the bonds became labile to chloroform—methanol. It was clear therefore that even if the main bonds between lipid and $\Pi_{\rm CM}$ were polar extra lipid was also bound weakly, was necessary for solubility and also exerted some protective action on the complex. A similar phenomenon has been observed by Das et al.¹² in model systems.

Das et al. have shown that cytochrome c, which is positively charged, binds phosphatidic acid ionically to form a salt, which is disaggregated in 0.1 molar potassium chloride. At lower ionic strengths the salt associates further, by apolar bonds, with unsaturated lecithins. In the resulting ternary complex the ionic bonds are buried, so that the complex, once formed, is unaffected by salts13 and soluble in iso-octane. Thus it seemed in the present case that either denaturation or chloroform-extraction of proteolipid removed similar "associated" lipids and thus exposed the polar lipid-protein bonds to the effect of the chloroform-methanol. Two valuable conclusions follow. First, because the proteolipid was unstable to chloroformmethanol unless already associated with extra lipids (and also because polar bonds could not form de novo in such a medium), the proteolipid could not be an artefact but must have pre-existed in the envelopes. Second, because the same proteolipid was obtained direct from live bacteria, it must also be presumed to exist in vivo.

The behaviour of the purple pellet (Π_D , Table 1) can be explained in the same way. The ratios of phosphorus to nitrogen in the isolated proteolipid (about 1:26) and in the purple pellet (1:21) were similar and in each case the chloroform—methanol extraction removed all the lipids. Yet if sufficient lipid was added to the purple pellet to make up the lipid content from a quarter to the original total, then (like Π_{CM} itself) Π_D became soluble in chloroform—methanol and stable. If we assume, as seems reasonable, that dialysis does not affect the polar bonds, then we must conclude that the weakly associated lipids were removed instead. As a consequence, the product became insoluble and unstable in chloroform—methanol unless these associated lipids were replaced beforehand. The effect of lowering the ionic strength by dialysis therefore is to re-order Π_D because of the repulsion between its negative charges Π_D . In then dissolves and because lipids remain bound to it hydrophobically, it removes all weakly bound lipids from Π_D .

Thus it appears that in vivo lipids are bound hydrophobically to one group of proteins, I, and by polar bonds to the other, II. Although it is uncertain whether a given lipid molecule is bound to both types of protein at the same time, much of the differently bound lipids must be in the same complex; otherwise, proteolipids could not be formed. The orange and purple fractions sediment together in a density-gradient centrifugation of the envelope-preparation (above) but in quite distinct bands after dialysis. This also is consistent with the view that proteins I and II are associated via the lipids. It was necessary therefore to identify the polar bonds.

Ionic bonds and hydrogen bonds were first considered. The ionic complexes between cytochrome c and phosphatidic acid, already referred to, would not form in 0·1 molar potassium chloride¹⁴. Even nucleoproteins, where there are many salt linkages between semi-rigid polyelectrolytes, are entirely dissociated in 3 molar potassium chloride. Yet H. halobium can live in 5·2 molar sodium chloride. One reasonable explanation, advanced by Brown¹⁵ on the basis of hydrogen ion titrations, is that the

lipid-phosphate moieties are linked to E-amino groups "buried" in the membrane and unavailable to the salt. Such bonds would, however, be metastable. The same objection would apply to the hydrogen bonds depicted by Brown¹⁵ because the proton in his diagram would certainly ionize from the phosphate to the amino-group and the bond would then be ionic, like the bonds in nucleohistones and in the complexes of Das. In this connexion, we found that urea had no effect on the protein lipid bonds, because the purple and orange fractions still sedimented together in a density gradient after treating an envelope-preparation with saturated urea. Again, the urea may not have penetrated to these bonds.

Salt-bridges were also considered. Morowitz, in a private discussion, pointed out to us that the magnesium concentration in the growth medium of *H. halobium* is significantly higher than that necessary for other organisms and, as in *Mycoplasma*¹⁶, suggested a specific role for magnesium ions. It has been shown that magnesium sulphate stabilizes the envelopes at low ionic strengths and also has other specific effects with Halobacteria^{17,18}. Salt-bridges (between phosphate, Mg²⁺ and negative groups on the protein) would be as labile to high ionic strengths as before, but further metal co-ordinate links in the form of a chelate complex are another possibility.

Hendrickson and Fullington¹⁹ have shown by titration experiments that phosphatidyl ethanolamine, phosphatidyl serine and triphosphoinositide form chelate complexes with Mg²⁺, Ca²⁺ and Ni²⁺, and Tasaki et al.²⁰ have suggested that a tricomplex exists between lipid, metal and protein in nerve membranes.

As Table 3 shows, the amino-acid: phosphorus: magnesium ratios were very suggestive. Corey, Pauling and Koltun²¹ space-filling models were constructed and show that chelates are sterically possible with the *H. halobium* lipid diphosphate (in which, as with the inositide, an oxygen rather than a nitrogen atom is the Lewis base).

One possible model for the link between the major lipid of *H. halobium* and protein II is therefore shown in Fig. 5.

Fig. 5. Possible binding between lipid and protein.

This represents a tetradentate inter-molecular chelate between groups on the protein, magnesium and the lipid head groups, together with an ionic link between the terminal phosphate and an arginyl group, to maintain neutrality. This particular model should be regarded as tentative because, first, model-building showed that the terminal phosphate group could also bind onto the magnesium, which then would have five ligands instead of four, and, second, the observed ratios do not correspond exactly with the model. It is possible that such strong bonding applies only to the diphosphate.

The chelate-hypothesis, however, accounts in a simple manner for the stability and specificity of the polar link in a high molarity salt environment. Moreover, the groups would be inaccessible, and their pK values also changed by the co-ordination, thus also accounting for the failure of amino groups to titrate in intact membranes¹⁵.

The chelation hypothesis would also account for the lability of the major lipid, the diether analogue of phosphatidyl glycerolphosphate, on denaturation. showed that while two protons titrate against sodium hydroxide in 50 per cent aqueous methanol with pK 3.25, the third titrates only partially in this solution with pK 7.45-7.95, and in pure methanol fails to titrate at all. When magnesium is bound in the complex it is therefore possible that the effect of denaturation is first to break the protein-magnesium bonds, leaving the magnesium bound to two charges on the lipid, and the lipid bound to the protein only by the third charge. The ionization is dependent, however, on the dielectric constant of the medium, and once the medium is able to penetrate to these bonds the ionization is lost and the lipid is removed. The observation of MacLeod et al.22, on H. cutirubrum, that after extensive dialysis this lipid is extracted as a 1:1 lipid-magnesium complex is entirely consistent with this explanation. Clearly, more detailed analysis (particularly of the ratio of magnesium to individual lipids in the complexes) and other tests will be necessary before the present model can be substantiated further and refined or, indeed, rigorously refuted.

It remains to discuss the question of the cell wall in *H. halobium* and some further observations on the purple fraction.

It is clear from the special electron microscope staining techniques of Stoeckenius and Rowen' that, contrary to the conclusions of Brown⁶, H. halobium is bounded by a labile cell wall which is isolated with the cell membranes. Although this adds a further complication to the system it does not invalidate the present conclusions about the bonding between lipid and protein. Their other observations are, however, very relevant. Plates of H. halobium usually gave chalky opaque colonies, while strain NCMB744, used by us, gave orange translucent colonies. It therefore seems likely that our strain is fortuitously a mutant. If it is accepted that the chalky appearance of inference is that strain NCMB 744 contains no vacuoles (as suggested by Stoeckenius and Rowen'), a possible inference is that strain NCMB744 contains no vacuoles and thus presumably none of the intracytoplasmic membranes seen by Stoeckenius and Rowen?. Our work therefore confirms their suggestion that the purple colour is associated with "the large membrane sheets" and not with the intracytoplasmic membranes. Furthermore, the purple protein, II, in our experiments was also found in the soluble proteolipid, Π_{CM} , and is therefore bound or associated with most of the lipid. This suggests that the "large membrane sheets" are in fact part of the cell membrane.

It was surprising in view of previous work that an insoluble component should remain at all after lysis. In our principal experiments, envelopes were isolated from cultures approaching the stationary phase, while in the experiments of Brown log-phase cultures were used. An experiment was therefore carried out by taking off a culture in early log-phase and working it up immediately.

It was then found that no purple component could be detected in the spectrum nor isolated after lysis (Table 1). A proteolipid, however, was still present in approximately the same ratio to the chloroform-methanol insoluble fraction as previously (Table 2). This suggested the possibility that the proteolipid fraction of the membrane cross-linked during the stationary phase and at the same time became purple, but the mechanism and biological significance of this are uncertain.

The nature of the purple colour is also unknown, although we confirm that a shift from 5630 Å to 3850 Å observed by Stoeckenius and Rowen, takes place on extracting the purple component with chloroform. It was also found that a reversible shift to 4800 Å occurred on treatment with very small amounts of chloroform followed by evaporation.

Conclusions

(1) The lipids of *H. halobium* are *in vivo* bound hydrophobically to one group of proteins, I, and by polar bonds to another, II. The differently bound lipids seem to be associated in the same complex.

(2) Firmly bound magnesium is present in the envelopes. The results of analyses show that it is possible to account for these results if the magnesium forms a chelate between groups on the protein and the lipid diphosphate head groups, together with an ionic link between the terminal phosphate and an arginyl group. Reasons have been given which make clear why such proposals must be regarded as tentative.

(3) An anomaly concerning the purple fraction has been clarified. The difference between the results of Brown, Stoeckenius and Rowen in this respect and our own early results arises from the fact that the purple colour of II_D exists only in fairly mature stationary phase cultures. It is non-existent in log-phase preparations. This complication does not invalidate our conclusions about the bonding between lipid and protein.

(4) The investigations described are essentially biochemical and their structural implications relate to the major bonding between lipid and protein components and not with their overall two- or three-dimensional array. No measurements have been made of the sizes of the lipid-protein complexes such as those of ID or IICM, but it is a reasonable hypothesis that the membrane is composed of a single layer of such complexes; the results of our experiments indicate that the layer of lipid binding the two types of protein together is primarily single (Fig. 6), not double as in the Davson-Danielli model of a complete membrane. A similar model has been suggested by Fleischer²³. Such a membrane would be structurally asymmetric, again in contrast to the Davson-Danielli model. This is a necessary condition for active transport. The electron microscope images of these two models (in transverse section), however, would in all probability differ only in the width of the lipid region. These remarks,

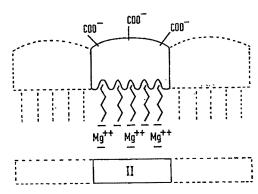

Fig. 6. Possible membrane model.

as so well shown in the recent review by Korn¹, only serve to emphasize the difficulties in the way of convincing proof, especially when dynamic concepts are taken into

Operational Identification of Schwarzschild Co-ordinates

by

W. DAVIDSON

Department of Mathematics, University of Otago, Dunedin, New Zealand

An operational interpretation of the standard Schwarzschild metric co-ordinates, r and t, is presented, together with a test of general relativity. This test employs the operationally defined co-ordinates L and T in place of r and t as the theoretical variables.

Our test of general relativity requires the use of two spacecraft each equipped with a radio pulse transmitterreceiver. One, the test body or planetoid P, is launched from the Earth so that it moves directly away from the Sun along an outward radius of the Earth's orbit, its initial velocity in the solar reference frame being a little in excess of v_B , the Earth's orbital velocity. This would require a rocket sufficiently powerful to generate a velocity relative to the Earth of approximately $\sqrt{2 \cdot v_E}$ after escape from the Earth's gravitational field. In one year's time the test body will have fallen back towards the Sun and be a distance of approximately half an astronomical unit from the Sun. At this time a second spacecraft, the control space station A, is launched from the Earth, so that, after escape, the Earth's orbital velocity is just cancelled and the space station is momentarily at rest in the solar reference frame. By firing suitably directed auxiliary rockets on both spacecraft, under command from Earth, it can be arranged that P falls radially towards the Sun, S, and A is kept approximately at rest in solar space, for the duration of the experiment, on the same radius SPand at a point on the Earth's orbit. The latter task will not be difficult provided the residual motion of A can be determined, because at a distance of one astronomical unit the gravitational acceleration caused by the Sun is only about 0.6 cm/sec2, while that caused by the Earth would fall below this order at an Earth distance exceeding 2×10^5 km.

The experiment involves sending successive microwave pulses from A to P. On arrival at P each pulse triggers an immediate response from the transmitter of P which is received by A. This allows the motion of P in L, T coordinates (described later) to be plotted and compared with the predictions of general relativity in the same co-ordinates. The experiment assumes that there is an atomic clock in the space station A, reading accurately,

say to one part in 1010, and that the events on the time-base in A can be stored and telemetered to Earth as required. The experiment can last for as long as there is fuel to keep the space station within the tolerance limits of motion.

It will be assumed that the gravitational field of the Sun can be described by the Schwarzschild metric in the

$$ds^{2} = \left(1 - \frac{2m}{r}\right)dt^{2} - \left(1 - \frac{2m}{r}\right)^{-1}dr^{2} - r^{2}d\theta^{2} - r^{2}\sin^{2}\theta d\phi^{2}$$
 (1)

with units chosen so that in the usual notation, c=G=1, and length is measured in km. For the Sun the gravitational radius, m, is approximately 1.5 km. Taking the world line of a test particle to be a geodesic of equation (1), the present case of interest is a radial geodesic $\theta = \pi/2$, $\varphi = 0$. Well known analysis yields for such a radial motion

$$\dot{r}^2 = \left(1 - \frac{2m}{r}\right)^2 - (1 - v^2) \left(1 - \frac{2m}{r}\right)^3 \tag{2}$$

where $r \equiv dr/dt$, and v is the velocity, real or imaginary, of the body in inertial space-time at infinity. In this analysis only terms up to order m/r ($\sim 10^{-8}$), and its equivalent in v^2 , will be retained. To this order, equation

$$\dot{r}^2 = v^2 + \frac{2m}{r} \left(1 - 3v^2 - \frac{4m}{r} \right) \tag{3}$$

The order of magnitude of the terms is seen clearly if we temporarily restore general units

$$\dot{r}^2 = v^2 + \frac{2\mu}{r} \left(1 - \frac{3v^2}{c^2} - \frac{4\mu}{c^2 r} \right) \tag{4}$$

where $\mu = GM_{\odot}$.

Suppose that a microwave pulse is transmitted from the space station, A, at co-ordinate time t_1 , reaches the planetoid, P, at co-ordinate time t and triggers an immediate response signal to arrive at A at co-ordinate time t_2 . Then the null geodesic hypothesis for light rays yields

$$t - t_1 = t_2 - t = \int_{r}^{R} \frac{\mathrm{d}r'}{1 - \frac{2m}{r'}} \sim R - r + 2m \log \frac{R}{r}$$
 (5)

where r is the radial co-ordinate of P at time t and R is the (constant) radial co-ordinate of A. The transmitterreceiver time-base of A, however, measures atomic time s_A , not co-ordinate time t_A . The relation between these, to the required order, is

$$\cdot s_A = \left(1 - \frac{m}{R}\right) t_A \tag{6}$$

By equations (5) and (6) therefore

$$R - r + 2m \log \frac{R}{r} = \left(1 + \frac{m}{R}\right) L$$

$$t = \left(1 + \frac{m}{R}\right) T$$
(7)

where

$$L = \frac{1}{2}(s_2 - s_1), T = \frac{1}{2}(s_1 + s_2)$$
 (8)

are operationally defined measures of position and time of the event P in terms of the atomic time of transmission and receipt of pulses at A. Retaining terms up to order L/R, and their equivalent in v^2 , straightforward substitution from equation (7) into equation (3) yields

$$\dot{L}^{2} = v^{2} + \frac{2m}{R - L} \left[1 - v^{2} + \frac{m}{R - L} \left\{ \frac{L}{R} - 2 \log \frac{R}{R - L} \right\} \right]$$
 (9)

where $\dot{L} \equiv \mathrm{d}L/\mathrm{d}T$. In general units this relation is

$$\dot{L}^2 = v^2 + \frac{2\mu}{R - L} \left[1 - \frac{v^2}{c^2} + \frac{\mu}{c^2 (R - L)} \left\{ \frac{L}{R} - 2 \log \frac{R}{R - L} \right\} \right]$$
 (10)

This operational equation, predicted by general relativity for radial motion towards the Sun, is to be compared with the corresponding Newtonian equation. Obviously, the same experiment can be interpreted in terms of Newtonian gravitational theory using Euclidean geometry and the assumption that the velocity of light in the solar reference frame is the constant c. Because the terms depending on c2 do not appear in the Newtonian analogue of equation (4), and because the terms in m do not appear in the analogue of equation (7), it follows that the corresponding Newtonian operational equation is exactly

$$\dot{L}^2 = v^2 + \frac{2\mu}{R - L} \tag{11}$$

It should be noted in particular that the differences between equations (10) and (11) arise from the complete Schwarzschild metric, equation (1). Thus equation (10), and also equation (14) further on, would be different if account was taken only of the coefficient of dt2 in equation (1), which might be inferred on the basis of the principle of equivalence alone. As regards keeping A at rest, it can be shown that the analysis described is valid to the order stated provided A does not move more than about $0.1~\mathrm{km}$ during the experiment. Thus very little auxiliary rocket control of the motion of A in the field of the Sun is needed in the conditions specified. The experiment could also be carried out with the planetoid, \vec{P} , outside the Earth's orbit falling towards the Sun at a distance of about 0.5 astronomical units from the station A, but this would require more launching power and the gravitational field on P would be weaker. Orbits to the Sun requiring less power but substantial correction in space have been discussed by Feenberg1.

With regard to the experimental distinction between equations (10) and (11), the co-ordinate R, as it occurs in equation (11), has been determined in the past from the Newtonian laws and Euclidean geometry. By such analysis relative distances within the solar system are known to perhaps one part in 108. But absolute distances on this basis depend on the practical measurement of the astronomical unit and it seems that this is known at present to only one part in 106 at most^{2,3}. Determination of the astronomical unit to one part in 108, however, may be expected on a Newtonian basis in the future. Indeed, experiments of the type suggested here would yield such an accuracy for R (at Earth perihelion, say), and thus for the astronomical unit, through equation (11). Obviously, because μ is known in terms of the astronomical unit to one part in 108 by the Keplerian law

$$\tau = \frac{2\pi a^{3/2}}{\mu^{1/2}} \tag{12}$$

(using an atomic clock to measure τ on the Earth), it follows that in equation (11) there are essentially only two unknowns, v^2 and R. Given sufficient data in the form of \dot{L}^2 , L number pairs both v^2 and R can therefore be determined in principle to one part in 108. The point is, of course that if the Newtonian theory is actually false to this order of accuracy then repeated experiments of this kind would not yield a consistent value of R for different

Equation (10) remains to be verified in which R is the Schwarzschild radial co-ordinate of a point on the Earth's orbit (Earth perihelion, say). By equation (1) this would differ from its Newtonian determination by a fraction of order m/R (or 10^{-8}). Once again, however, μ is known to this order in terms of R even in the relativistic case. For the orbit of a planet, according to equation (1), is known to be a slowly rotating ellipse the orbital period τ of which (from perihelion to perihelion) may be shown to be

$$\tau = \frac{2\pi a^{3/2}}{\mu^{1/2}} \left[1 + \frac{m(3-e^2)}{2a(1-e^2)} \right]$$
 (13)

where a is the r co-ordinate length of the semi-major axis, m is the parameter of equation (1) and e is the eccentricity of the ellipse. Because the term in square brackets is known to the required order even at present, it follows that an atomic clock value of τ gives μ relativistically in terms of a (and hence R) for the Earth. Thus in equation (10), also, there are essentially only two unknowns, R and v^2 , and so repeated experiments with different values of v^2 should give a consistent value for Rif general relativity is correct.

Finally, suppose it became possible, as undoubtedly it will in the future, to generate in a small instrumented probe, P, a value of v in the hyperbolic range, as high as 300 km/sec. Then v^2/c^2 is of order 10^{-6} , and the third term in the bracket of equation (10) is less than this by a factor of 100. In this case the relativity equation approximates

$$\dot{L}^2 = v^2 + \frac{2\mu}{R - L} \left(1 - \frac{v^2}{c^2} \right) \tag{14}$$

and now even a Newtonian determination of R to one part in 107 would be adequate to establish whether equation (14) was a better fit than equation (11).

LETTERS TO THE EDITOR

ASTRONOMY

Variability of Centaurus XR-2

Chodil et al. have suggested that the X-ray flux from the Centaurus XR-2 object varied between 1965 and 1967. In this communication we give in detail the changes in X-ray emission which occurred during the period April—May 1967, and show that during this time the X-ray energy output decreased approximately exponentially as a function of time, with a time constant of 25 days.

The data were obtained by X-ray detectors flown on two Skylark rockets, launched from Woomera at 0032 UT on April 4, 1967, and 2236 UT on April 20, 1967, and from an experiment¹ flown from Hawaii by the Levermore Research Laboratory (LRL) group on May 18, 1967. The Skylark results have been presented previously², the presence of a strong X-ray source near the constellation Crux being reported at that time. Re-analysis of our aspect data has resulted in a revision in our position for this source to a mean value of 13.9 h right ascension, -64° declination, which places it barely within the boundary of the constellation Centaurus. The LRL flight detected a source within 4° of this position and referred to it as Centaurus XR-2. We take the view that the LRL and Universities of Adelaide and Tasmania (UAT) observations refer to the same object, and propose to adopt the LRL nomenclature.

The Skylark detectors consisted of two independent pairs of xenon-methane filled, proportional counters with beryllium windows. The spectral information from the detectors consisted of the counting rates from two energy bands, 2-5 keV and 5-8 keV. Assuming a photon

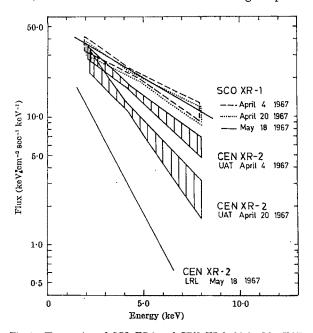

Fig. 1. The spectra of SCO XR-1 and CEN XR-2 obtained by UAT on April 4, 1967 (day 94), and April 20, 1967 (day 110), are shown. The uncertainties in the intensity and temperature of the spectra are indicated. Also shown are the spectra obtained by LRL on May 18, 1967 (day 188). Note that there is good agreement between the three measurements of the SCO XR-1 spectrum, while there is a great divergence between those of CEN XR-2.

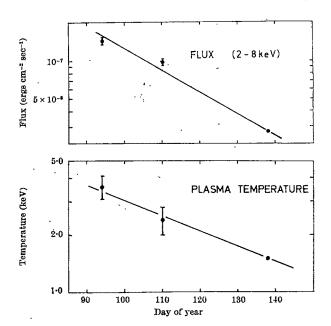

Fig. 2. The temporal decrease in the 2-8 keV energy flux and the effective plasma temperature of CEN XR-2 are shown. The UAT spectra were taken on days 94 and 110, the LRL spectrum on day 138.

spectrum which corresponds to free-free emissions from a thin hot plasma of temperature T,

$$rac{\mathrm{d}N}{\mathrm{d}E} = J_0 \cdot E^{-1} \cdot \exp(-E/T) \; \mathrm{photons \cdot cm^{-2} \; sec^{-1} \; keV^{-1}}$$

and taking into account window thickness, counter efficiency, pulse height resolution, and the counter and effects, the expected counting rate in each channel was calculated for various values of the plasma temperature, T. The ratio of the two counting rates is then a function of T, while the total counting rate in the 2–8 keV energy range is a function of J_0 . In this manner, the spectra giving the best fit to the observed data were obtained for both flights, for both $SCO\ XR$ -1 and $CEN\ XR$ -2.

The results of these calculations and the spectra quoted by Chodil et al. are shown in Fig. 1. The excellent agreement between the three independent measurements of the SCO XR-1 spectrum indicates that the data and the spectra derived from all three flights are strictly comparable. Figure 1 shows, however, that the CEN XR-2 spectra differ greatly from one flight to the next, the fluxes decreasing monotonically with time. This conclusion is not dependent on the assumption of a free-free spectrum; the same qualitative conclusion is reached by comparing the ratios of the observed counting rates from CEN XR-2 and SCO XR-1, or from the assumption of any other reasonable spectra. Furthermore, both the UAT and the LRL detectors, because they employ collimators with wide cones of acceptance in the plane containing the spin axes of the rockets, are not subject to the introduction of spurious time variations through errors in the correction for the collimator response at non-normal photon incidence.

Figure 2 shows the total energy flux in the 2-8 keV energy range, and the calculated plasma temperatures, T, as functions of time. It is clear that both exhibit very marked time dependence. The upper curve (which is derived directly from the observed data with the introduction of a minimum of assumptions) approximates an exponential of time constant 25 days. The lower curve indicates that the decrease in energy output is accompanied by a coftoning of the X-ray energy.

panied by a softening of the X-ray spectrum.

Chodil et al.¹ have reported that CEN XR-2 was not detected in 1965, while Figs. 1 and 2 indicate that on April 4, 1967, it was comparable with SCO XR-1, the brightest object in the X-ray sky. This fact, plus the

temporal dependence indicated by Figs. 1 and 2, establish in a completely unambiguous manner that CEN XR-2 is a variable X-ray object. The data do not make it possible to determine whether it is a periodic or an aperiodic variable; however, the fact that all X-ray observations to date indicate either constancy (for example, SCO XR-1, TAU XR-1) or drastic, short lived change (CEN XR-2) suggests the variability is transient. The observed decay time constant of 25 days agrees within a factor or two with the decay time constants of type II supernovae, suggesting some similarity in the phenomena. The fact that $CEN\ XR$ -2 lies within a few degrees of the galactic disk, and therefore in a region of considerable optical obscuration, means that any optical counterpart of the X-ray variability may have escaped detection.

The possibility has been considered that CEN XR-2 and the very weak \tilde{CEN} XR-1 source, discovered by Friedman et al.3 in April 1965, are, in view of positional uncertainties, one and the same object. Even if this were so, the source intensity must have changed by two orders of magnitude between 1965 and 1967, and the basic conclusions given here remain unaltered.

The initial Universities of Adelaide and Tasmania X-ray detector hardware development was performed at the Southwest Center for Advanced Studies, Dallas, Texas, under a NASA contract. R. J. F. and J. R. H. acknowledge the support provided by Commonwealth and CSIRO postgraduate scholarships, respectively. We thank the Science Research Council for providing the opportunity to make these flights and the personnel of BAC, Filton, UK, and of the Aerodynamics Division of the Weapons Research Establishment, Salisbury, Australia, for their help.

Blackbody Radiation and the Eddington-Lemaître Universe

THE discovery of the isotropic cosmic background radiation in the universe¹ and the subsequent demonstration by various groups of its blackbody spectrum have generally been taken to imply that the universe is of the type characterized by a big bang. Such models, containing both radiation and matter, have recently been examined in detail by McIntosh² and Jacobs³.

This communication shows that such radiation could also be present in a universe which is of the Eddington-Lemaître type⁴—that is, which expands from a finite static state in the infinite past. In contrast to the hot models mentioned, and the cold model described by Zeldovitch, the modified Eddington-Lemaître model proposed here might be termed the cool model, because for reasonable values of the parameters involved, the temperature of the radiation is always quite low.

We begin with the field equations of general relativity in the form

$$8\pi G \rho = \frac{3}{R^2} (kc^2 + \dot{R}^2) - \Lambda \tag{1}$$

$$8\pi G \frac{p}{c^2} = -\frac{2R}{R} - \left(\frac{R}{R}\right)^2 - \frac{kc^2}{R^2} + \Lambda$$
 (2)

where R(t) is the scale-factor of the Robertson-Walker metric, Λ is the cosmological constant, and k, the spatial curvature index, is taken to be +1. The pressure and density are contributed by both matter and radiation so that

 $\rho = \rho_m + \rho_r$

$$p = p_m + p_r$$

Denoting present conditions by a subscript 0 and conditions in the static state by s, we have

$$\frac{R_0}{R_0} = 1 + z_{\text{max}} \equiv Z \tag{3}$$

$$\rho_{m,s} = Z^3 \rho_{m,0} \tag{4}$$

and

and

$$\rho_{r,s} = Z^4 \, \rho_{r,0} \tag{5}$$

Introducing the assumption that the static state was one of thermodynamic equilibrium makes it possible for us to define a unique temperature

$$T_s = Z T_0$$

where T_0 is the present temperature of the blackbody radiation. One might note parenthetically that the radiation would play the part of the heat reservoir of classical thermodynamics, as pointed out by Gamow⁶.

Then, assuming the matter to follow the perfect gas law, we find

$$p_{s} = \frac{\rho_{m,s} kT_{s}}{\mu H} + \frac{\rho_{r,s} c^{2}}{3}$$

$$= \rho_{m,s} Z \left[\frac{kT_{0}}{\mu H} + \frac{c^{2} \rho_{r,0}}{3 \rho_{m,0}} \right]$$
(6)

Now.

$$\frac{\rho_{r,0}}{\rho_{m,0}} = \frac{a T_0^4}{c^2 \rho_{m,0}} = F$$
, say.

If $\rho_{m,0} = 5 \times 10^{-31}$ g/cm³ and $T_0 = 3$ °K, $F = 1.36 \times 10^{-3}$. Because the first term of equation (6) is of order 108 and the second term is of order 1017, we can obviously say that

$$p_s = \frac{c^2}{2} FZ \rho_{m,s} \tag{7}$$

It follows from equations (4) and (5) that

$$\rho_s = \rho_{m,s} (1 + FZ) \tag{8}$$

Substituting from equations (7) and (8) into (1) and (2) and remembering that in the static state $R = \ddot{R} = 0$, we find

$$\Lambda = \left(\frac{1+2 FZ}{3+4 FZ}\right) \frac{3 c^2}{R_z^2}$$
 (9)

If F were zero this would be the relation found by Lemaître.

At the present time the ratio of pressure to energy density is small,

$$\frac{p_{\rm 0}}{\rho_{\rm 0}\,c^2}\,=\,\frac{\alpha\,T_{\rm 0}^4}{3\,c^3(\rho_{\rm m,0}\,+\,\rho_{\rm r,0})}\,\sim\,5\times10^{-4}$$

so that in applying equations (1) and (2) now we may write7

$$\Lambda \tau_0^2 = 3(\sigma_0 - q_0) \tag{10}$$

and

$$\frac{c^2 \tau_0^2}{R^2} = 3\sigma_0 - 1 - q_0 \tag{11}$$

where $\tau_0 = H^{-1}$, $\sigma_0 = \frac{4\pi}{3} G \rho_0 \tau_0^2$ and q_0 is the acceleration factor. Combining equations (3), (9), (10) and (11) yields

$$2F(3\sigma_0 - 1 - q_0)Z^3 + (3\sigma_0 - 1 - q_0)Z^2 - 4F(\sigma_0 - q_0)Z - 3(\sigma_0 - q_0) = 0$$
(12)

which specifies Z when σ_0 and q_0 are known. It is possible to find an exact expression for R (t) in this model by noting that

$$\rho(t) = \rho_{m,s} \left(\frac{R_s}{R}\right)^s + \rho_{r,s} \left(\frac{R_s}{R}\right)^4 \tag{13}$$

and that

$$R_{s^{-2}} = 4\pi G c^{-2} \rho_{m,s} \left(1 + \frac{4}{3} FZ \right)$$
 (14)

Making use of equations (4), (5), (13) and (14) in (1) and introducing

$$x = (R - R_s)/R_s$$

leads, after integrating and taking the constant of integration to be zero, to

$$ct R_{\star}^{-1} (3 + 4 FZ)^{-1/2} =$$

$$(1+2 \ FZ)^{-1/2} \log \begin{cases} [x^2(1+2 \ FZ) + 4x(1+2 \ FZ) \\ + 3 + 8 \ FZ]^{1/2} + x(1+2 \ FZ)^{1/2} \\ + (1+2 \ FZ)^{-1/2} (2+4 \ FZ) \end{cases}$$

$$- (3 + 8 FZ)^{-1/2} \log \begin{cases} x^{-1}[x^{2}(1+2 FZ) + 4x(1+2 FZ) \\ +3+8 FZ]^{1/2} + x^{-1}(3+8 FZ)^{1/2} \\ +(3+8 FZ)^{-1/2} (2+4 FZ) \end{cases}$$
(15)

It follows from equation (15) that

$$q_{0} = -\frac{\ddot{R}_{0}R_{0}}{(\dot{R}_{0})^{2}} = -\frac{1}{x_{0}}$$

$$-\frac{(1+x_{0})(2+x_{0})}{x_{0}^{2}+4x_{0}+(3+8\ FZ)(1+2\ FZ)^{-1}}$$
(16)

and so $q_0 \leq -1$. Furthermore,

$$x_0 = \frac{R_0}{R_s} - 1 = Z - 1$$

so that, in principle, by substituting from equation (16) into equation (12), Z can be found once σ_0 is specified. In practice an iterative procedure was used. Starting with the values of σ_0 and F corresponding to $\rho_{m,0} = 5 \times 10^{-31}$ g/cm³, H = 100 km/sec/Mparsec, $T_0 = 3^{\circ}$ K, and assuming $q_0 = -1$, a value of Z was calculated from equation (12). This value of Z was then used in equation (16) to determine a result of $q_0 = 1$. determine a new value of q_0 , and the procedure repeated. The process converged rapidly to

$$q_0 = -1.1377$$

$$Z = 4.3972$$

If, therefore, $T_0 = 3$ °K, then $T_s = 13.2$ °K. Also the maximum red-shift observable in this model is $z_{\text{max}} = 3.3972$.

It will be noted that the value of q_0 given is lower than the range of values usually considered probable, $0 \le q_0 \le 2$. In view of the present state of knowledge (or ignorance) of the stellar content of elliptical galaxies and the possible evolution of these galaxies, this is not considered a serious drawback.

There are a number of other features of this model which deserve comment. In the first place, the ultimate question of origins is avoided, because the universe has existed for an infinite time. Second, the density of matter is given by the observed value ($\sim 5 \times 10^{-31} \, \text{g/cm}^3$) and yet the curvature of space is positive; thus the Machian aim of many authors is achieved without the necessity of postulating unobserved matter. Finally, it should be noted that the

chemical composition of the static state has been left unspecified. If it should happen that old, helium-deficient stars are founds, this model would be particularly attrac-

Cosmic Blackbody Radiation and Isotropic Gamma Rays: a Contradiction?

In his article on the isotropic gamma ray background. Cheng¹ presents instructive calculations of the production and propagation of inverse Compton gamma rays in an expanding universe. The latter part of the paper, however. includes a rather arbitrary application of these results which leaves the impression that there is some conflict between the observed X-ray and gamma ray background and the popular blackbody (3° K) interpretation of the observed microwave background. The purpose of this communication is to reassure big bang theorists that this is emphatically not the case.

X-rays and gamma rays are, certainly, produced in Compton collisions of blackbody photons with the intergalactic population of fast electrons^{2,3}. Unfortunately, we have no direct evidence as to the number density or energy spectrum of these electrons. Cheng assumes that the intergalactic electrons have a spectral shape like that of primary cosmic ray electrons near the Earth' and a number density a hundred times smaller. From such a large electron flux there necessarily follows an isotropic gamma ray intensity well in excess of the observed spectrum. Cheng makes much of the discrepancy, but in suggesting that it might be resolved if the density ratio could be chosen as 104 instead of a hundred he cannot but underscore the essentially arbitrary character of this approach. Morrison and I5 investigated sources of fast electrons and showed that, far from producing too many gamma rays, the intergalactic electron density could only with some theoretical discomfort be brought up to the level required to account for the observed gamma rays by the inverse Compton mechanism. (R. J. Gould has pointed out to me that it is interesting though not necessarily significant that injection adequate to this end is obtained by way of electron secondaries produced in the intergalactic π - μ -e process if the cosmic rays are universal and the mean density of matter is about 10-5 particles cm⁻³. If we must instead rely for electron injection on leakage from radio galaxies, the required level is problematical5,6.)

Because we discussed sources we were also able to study the equilibrium electron spectrum and show that the resulting gamma ray spectrum should be steepened by the large Compton loss caused by the blackbody photons^{2,5}. This brought the predicted spectral shape into agreement with the observations and was an improvement over earlier and more arbitrary calculations3, as we pointed out5. Cheng has now reverted to the arbitrary method; he presents his predicted spectral shape and the contrasting observational curve on a common graph in Fig. 3 but makes no comment on the discrepancy in slope, although he is aware of the paper by Morrison and myself, having cited it in another connexion. This is a step backward.

Neither our work nor that of Cheng takes proper account of the effects that rapid evolution of galaxies or radio sources may have on the isotropic X-ray and gamma ray background. That these effects may be sizable has recently been demonstrated (ref. 7; see also forthcoming papers by Silk and Bergamini, Londrillo and Setti). It is also quite possible in any case that most of the diffuse gamma ray background originates in unresolved discrete sources in galaxies (ref. 8 and unpublished results of Silk and Bergamini et al.) rather than in intergalactic space. A good deal of work remains to be done, but it is now clear that there is no apparent contradiction between the observations of isotropic gamma rays and the assumption that the universe is filled with equilibrium blackbody radiation having $T \approx 3^{\circ}$ K at the present epoch. Indeed, to whatever extent the gamma radiation is relevant, its high intensity and steep spectrum tend even to favour the blackbody hypothesis (refs. 2 and 5 and unpublished result of Bergamini et al.).

Correlation between Sudden Cosmic Noise Absorption and Solar Radio Bursts observed at Five Microwave **Frequencies**

The 10.7 cm index of solar activity has been used for many studies of solar-terrestrial interactions. principal reason for this is that highly accurate data The present extending back to 1947 are available. availability of accurate information at other microwave frequencies makes it possible to determine the relative

effectiveness of these frequencies as indices of solarterrestrial relations.

Basu and Karmakar¹ studied the correlation of 10.7 cm mean solar flux and 10.7 cm solar radio bursts with sudden cosmic noise absorption (SCNA) events. In this communication we shall report the results of a correlation study of solar radio data collected at five different frequencies: 606 Mc/s, 1,415 Mc/s, 2,695 Mc/s, 4,995 Mc/s and 8,800 Mc/s, by personnel of the Air Force Cambridge Research Laboratories² at the Sagamore Hill Radio Observatory, Massachusetts, during 1966, and sudden cosmic noise absorption data covering the same period, published by the Environmental Science Services Administration. An average of approximately sixty SCNA events occurred during the Sagamore Hill operating hours in 1966.

Table 1					
Freq.	No. of	No. of	No. of corre-		
(Mc/s)	SCNA	bursts	lated events		
606	69	245	20		
1,415	69	243	26		
2,695	55	251	25		
4,995	40	163	21		
8,800	54	219	28		

A time delay, T, is defined as the difference between the onset time of an SCNA and that of a corresponding solar radio burst. The criterion adopted for considering these two events as correlated was that the time delay, T, should not exceed -10 or +15 min. (A negative T which occurs roughly 15 per cent of the time indicates that the start of the SCNA precedes the start of the burst.) Data available for consideration are listed in Table 1. The information in column 3 of Table 1 was further reduced to burst intensity groups within certain limits, for example, 1-5, 5-15, 15-45, 45-150, 150-450, and > 450 flux units of 10^{-22} W m⁻² (c/s)⁻¹. Figure 1 is a plot of the ratio of these bursts correlated with SCNAs to the total number of bursts observed within the given range of peak flux intensities. Curve (a) is an average of the decimetre observations at 606 Mc/s and 1,415 Mc/s, and curve (b) is an average of the centimetre observations at 2,695 Mc/s, 4,995 Mc/s and 8,800 Mc/s. Both curves show poor correlation for bursts weaker than 15 flux In the decimetre region (curve a) the ratio of bursts correlated with SCNAs improves only slightly with increased burst intensity, and then starts to decrease, while in the centimetre region (curve b) the ratio increases with burst intensity and reaches unity for bursts greater than 450 flux units.

If only bursts with peak flux densities greater than 15 units are considered and the correlation as a function of frequency is studied, we obtain results shown in Fig. 2.

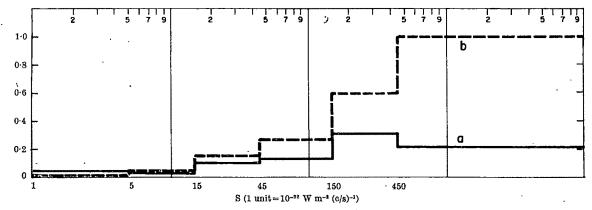

Fig. 1. Ratio of bursts correlated with sudden cosmic noise absorption events to the total number of bursts in each peak flux interval for (a) 606 Mc/s and 1,415 Mc/s, and (b) 2,695 Mc/s, 4,995 Mc/s and 8,800 Mc/s.

Here we have plotted (a) the ratio of the number of coincidences to the total number of SCNAs and (b) the ratio of coincidences to the number of bursts with peak intensity greater than 15 flux units. By so limiting burst data, the number of burst samples used was reduced by about 50 per cent from the numbers given in Table 1 but the number of coincidences was reduced only slightly. We see that correlation increases with frequency; at 8,800 Mc/s it is about twice that at 606 Mc/s.

Spectra of the increase of burst peak flux for thirty-two radio events correlated with SCNAs were plotted; four had incomplete spectra and were not used. Their intensities covered a wide range. The most common shape (fifteen out of thirty-two) had a positive gradient; that is, the flux increased toward the higher frequencies and showed no activity at the lower frequencies. There were sixteen other spectral curves with various undulating shapes, not classified at this time. Only one event was found with a negative gradient and no activity at the higher frequencies.

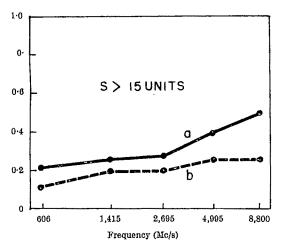

Fig. 2. Ratio of coincidences (a) to sudden cosmic noise adsorption events, and (b) to bursts Peak flux intensity is greater than 15 units.

The preliminary survey of the data shows that about half of all radio burst spectra has a positive gradient. (This spectral type is described by Kundu⁴ as not having associated activity at metre wavelengths.) The same proportion is also found in the thirty-two spectra of bursts that are correlated with SCNAs. About one out of every six bursts has a negative gradient and shows no activity in the short centimetre region, but only one of the thirty-two correlated bursts was in this category. This explains the poor correlation found at the lower frequencies of the decimetre region in Fig. 2 and in curve (a) of Fig. 1 for peak flux densities greater than 450 units. In the latter case only five of the twenty-three events observed at the two decimetre wavelengths with fluxes greater than 450 units were correlated with SCNAs, while all nine events observed at the three centimetre wavelengths at this flux level were correlated (see Fig. 1, curve (b)). Thus for bursts in the centimetre region with high intensities there is practically 100 per cent correlation while in the decimetre region the correlation of bursts with high intensities is only about 20 per cent.

It is known that SCNAs are produced by solar X-rays ionizing the *D* region of the ionosphere. Kundu⁵ suggests that X-rays and centimetre bursts are produced by the same electrons. The absence of correlation of SCNAs with bursts, having no activity in the centimetre region, suggests therefore that no X-rays are emitted with those bursts. The important result of this study is that solar radio bursts and SCNAs show an improving correlation

as the monitoring frequency of solar microwave bursts increases from 606 Mc/s to 8,800 Mc/s.

Limits on Small Scale Variations in the Cosmic Background Radiation

The 3° K microwave background radiation¹⁻⁵ left over from the big bang, in which the universe is supposed to have originated, would exhibit features of small angular size if at the time of the escape of the radiation there were density inhomogeneities. Observational evidence for, or limits to, such non-uniformity bears directly on important questions, including the origin of galaxies' and their magnetic fields8.

We have previously reported limits on the root mean square temperature fluctuation, σ , of 5·1 millidegrees K at an angular scale of 1°, and 3.6 millidegrees K at a scale of 6°, measured over a small region of the sky, and limits at a scale of about 15° are deducible from the observations of Wilkinson and Partridge¹⁰. We have recently concluded a survey of a larger section of sky, and can now set reduced upper limits to σ for scales of up to 2°.

The receiver used was a conventional 'Dicke' radiometer, and has been described previously⁹; the system noise temperature was about 800° K and the antenna beamwidth was about 10 min of arc at 10,690 Mc/s. Data were taken digitally at 10 sec intervals; addition of data from successive days for corresponding sidereal times and further processing were done by computer. Figure 1 shows the results of adding 36 days of observations in June and July 1967; no corrections have been made to the observed data. The receiver was calibrated by a gas-discharge tube. Where the plane of the galaxy passed through the beam, radiation

Observed temperature averaged over 36 days. Antenna beamwidth=10 min, declination=+40.6°.

was received from the well known radio sources Cygnus A and Cygnus X, which provided a check on the receiver each day. The long-term drift in the record is the result of ambient temperature variations; it was removed by subtracting the half-hour running average from the data.

Over the region of sky from 11 h to 19 h right ascension the root mean square fluctuation of the 36 day record. $\sigma_{\rm obs}$, was found to be 5.6 millidegrees K (with a standard deviation of 0.19 millidegrees estimated from the variation from hour to hour). Figure 2 shows $\sigma_{\rm obs}$ for 1, 4, 10, 16, 25 and 36 day records. We would expect $\sigma_{\rm obs}$ to first diminish as $n^{-\frac{1}{2}}$, where n is the number of days, and then approach a horizontal asymptote determined by the small-scale background variations. The broken line, which is a curve of the expected form fitted to the data, shows that in the area of sky surveyed with the beamwidth of 10 min of arc, the asymptotic value can hardly exceed 3.6 millidegrees K.

Even lower upper limits can be set by integrating the original data so as to simulate records which would have been obtained with a wider antenna beam. For example, σ_{obs} obtained from the 36 day record with a simulated beamwidth of 2° is 1·7 millidegrees K, from which the upper limit to the asymptotic value is found to be 1·5 millidegrees K. Little information is available at resolutions coarser than 2° because receiver drift introduces confusion.

Upper limits can also be set to the strength of features much finer in angular scale than the antenna beam. Let the temperature be T(x,y) over a patch of sky and let t(x,y) be the departure from the spatial average

$$t(x,y) = T(x,y) - \langle T(x,y) \rangle$$
 (1)

The intrinsic fluctuations in the temperature distribution, T(x,y), as distinct from the fluctuations observed after averaging over the beam of an antenna, can be characterized by an intrinsic fluctuation level σ , where

$$\sigma = \langle [t(x,y)]^2 \rangle^{\frac{1}{2}} \tag{2}$$

Let the spatial variation of temperature be characterized statistically by a two dimensional spatial autocorrelation function $\gamma(\theta)$ defined by

$$\gamma(\theta) = \frac{\langle t(x,y)t(x+u,y+v)\rangle}{\langle [t(x,y)]^2\rangle}$$
(3)

which is a function of θ only, where $\theta^2 = u^2 + v^2$. Then the spatial distribution may be characterized by a one dimensional scale size that is constant over the patch of sky and independent of orientation. We define the "scale" Θ by

$$\Theta^2 = 2\pi \int_0^\infty \gamma(\theta)\theta d\theta \tag{4}$$

choosing this particular definition in order to make equation (6) valid for any form of dependence of

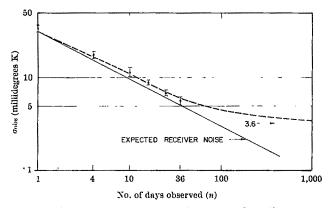

Fig. 2. Observed root mean square temperature fluctuation, $\sigma_{\rm obs}$, against number of days, n. The total length of an error bar is five times the standard deviation of the mean.

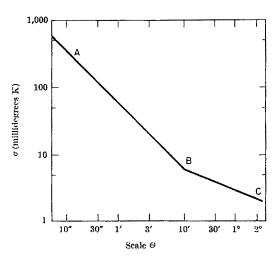

Fig. 3. Intrinsic fluctuation σ against scale Θ.

 γ on θ . If the power reception pattern of the antenna is A(x,y), that is when the antenna is pointed at (0,0) the response to a point source at (x,y) is A(x,y), then an effective beamwidth, B, can be defined by

$$B^{2} = \frac{\left[\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} A(x,y) dx dy\right]^{2}}{\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} [A(x,y)]^{2} dx dy}$$
 (5)

Now if the patch of sky is mapped by the antenna, then σ_{obs} will be less than σ and can be shown to be given by

$$\sigma_{\text{obs}^2} = \sigma^2 \left(\frac{\Theta}{\Theta'}\right)^2 + \sigma_R^2 \tag{6}$$

where σ_R is the root mean square fluctuation resulting from the internally generated receiver noise, and Θ' is the quantity that is analogous to Θ but refers to the two dimensional spatial autocorrelation function of the convolution of t(x,y) and A(x,y).

For example, if t(x,y) has a Gaussian autocorrelation function, $\gamma(\theta) = \exp(-\theta^2/2S^2)$, then $\theta = 2.51S$, and if the antenna pattern is also Gaussian with a half-power beamwidth (W), $A(x,y) = \exp[-(x^2+y^2)/0.36W^2]$, then B = 1.51 W and $\theta'^2 = \theta^2 + B^2$. In this observation W = 10 min of arc, σ_R is calculated from the receiver parameters and the data processing to be 5 millidegrees K, and σ_{obs} is 6.1 millidegrees K, as read from the broken line at n = 36 in Fig. 2. A graph of σ versus θ , from equation (6) with these constants, is shown in Fig. 3 (section AB). Because the quantity previously referred to as the asymptotic value is the term $\sigma^2(\theta/\theta')^2$ in equation (6), conclusions regarding coarser scales obtained by simulating wider antenna beams can now also be presented in Fig. 3 (section BC). To summarize.

$$\sigma = \begin{cases} 61 \, \theta^{-1} & 0 < \theta < 10 \\ 19 \, \theta^{-\frac{1}{2}} & 10 < \theta < 120 \end{cases}$$
 (7)

where σ is in millidegrees K and Θ is in min of arc. The fractional error in section AB is the same as at B but in section BC increases approximately as $\Theta^{\frac{1}{2}}$.

At low frequencies and comparable beamwidths the root mean square fluctuation produced by the many faint discrete sources exceeds the limits given here; at 610 Mc/s a root mean square "confusion noise" level of about 16 millidegrees K has been measured in a 16 × 22 min of are beam¹¹. Extrapolation to 10,690 Mc/s indicates that it may not be possible to reduce appreciably the upper limits to a reported here. The spectra of the faint sources, however, are not sufficiently well known for one to be sure about this.

PLANETARY SCIENCE

Orogeny, a Cause of World-wide Regression of the Seas

In has often been suggested that orogenic episodes and epochs of folding coincide with world-wide regressions, and I wish to put forward a simple explanation of why this should be so.

I have constructed a model to represent two continents "floating" on the mantle and just submerged by the sea (Fig. 1). The continents are represented by rectangular blocks of lead floating in a trough of mercury. Water is poured onto the mercury so that the "continents" are just submerged. The "continent" can be deformed and a mountain created by halving the width and doubling the thickness of the mobile belt; in practice this can be done by cutting one block in half and turning one of the halves on its side. The deformed "continent" will displace the same amount of mercury although the mountain will have a deeper root, and so the level of the mercury will remain the same, but the water now has a larger area to spread over and so the depth of the water will drop and the stable "continent" will emerge from the "sea".

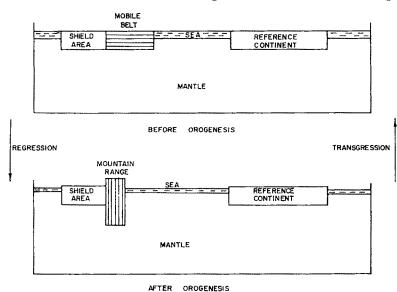

Fig. 1. Schematic diagram showing effect of orogenic episode on sea level.

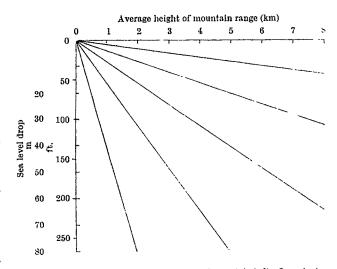

Fig. 2. Sea-level changes due to formation of mountain belt. Length of mountain range (width 300 km): 1, 2,000 km; 2, 5,000 km; 3, 10,000 km; 4, 20.000 km; 5, 50,000 km.

At first sight, the effect seems negligible, but if it is considered that most of the continental crust is transformed into the mountain root, to maintain isostatic equilibrium, the effect can be appreciable. An increase of only I per cent in the area of the oceans would lower the sea level by 40 m, assuming an average depth for the oceans of 4 km. Woollard has shown that a change in surface elevation of 1 km corresponds to a change of 6.8 km in crustal thickness. This means that if continental crust of an assumed average thickness of 35 km is transformed into a mountain range 3 km high, a root of about 20 km must exist, giving the resultant thickness of the crust as 58 km. It follows that a mountain range $5,000 \mathrm{\ km}$ long of average width and height (300 and 3 km, respectively) must have originated from crustal material approximately 500 by 5,000 km. This is a net increase in the total area of the oceans of 106 km2. If the area of the oceans is 311 × 106 km² (ref. 2) the sea level must drop everywhere by 13 m (40 ft.).

If orogenic episodes in different continents took place at the same time, a drop in the sea level of more than 100 ft. could easily be envisaged. Erosion of the mountains and the rest of the land would immediately increase. and sediments deposited in the sea would cause it to rise and transgress over the continents. Figure 2 shows in

idealized form the change in sea level caused by mountain belts, of different

lengths and heights, forming.

From the stratigraphic record in one area of a continent it is difficult to obtain an overall picture of the state of the seas with time, because a local transgression can occur while there is a world-wide regression of the sea3. By considering the whole of one continent, a much better picture can be obtained. Schuchert's palaeo-geographic maps of North America are ideal for this purpose and from these maps it is possible to plot a curve of the percentage area of epicontinental seas with time. Damon and Maugers have recently done this for periods from the Triassic until the present time, and Fig. 3 shows an adapted form of their curve. Kuenen⁶ considers that the more extensive transgressions did not involve a rise of much more than 600 ft. On this basis the increase in depth of the sea with respect to the present level has been plotted.

Table	1. OROGENIC EPISODES	
North American	Name of episode	Reference
NA 1	Pasadenan	5
NA 2	Basin and Range	
NA 3	Laramide	5
NA4	Santa Lucian	5 5 5 5
NA 5	Nevadan	5
NA 6	Palisadean	5
European		
$E\vec{U}$ 1	Alpine	14
EU 2	Pyrenean	13
EU 3	Austrian	13
EU 4	Young Kimmerian	13.
EU 5	Old Kimmerian	13
New Zealand		
NZ 1	Kaikoura	15
NZ 2		15
NZ 3	Rangitata	15
NZ 4	Rangitata	15

Does this curve represent accurately the world-wide trends? Certainly the Cretaceous transgression shows up clearly, as does the subsequent regression. The Eccene transgression and the Miocene transgression are also well documented. The mid-Jurassic is known to be transgressive in Australia, Europe and North America⁸ and it seems unlikely that the late Jurassic regression in North America, which affected about 15 per cent of the continent, could not have affected the world as a whole. It is unfortunate that sufficiently detailed palaeogeographic maps of other continents are not available for comparison with these data. The curve of Fig. 3 is believed, however, to represent the trends and to be of world-wide sig-

Apart from the overall Mesozoic transgression, which commenced at the beginning of the Triassic and ended in late mid-Cretaceous time, short term regressions and transgressions, superimposed on the general trends of the curves, are apparent. Damon and Mauger⁵ have correlated six distinct orogenies in the North American continent with the short periods of regression. If these oscillations are the results of the orogenies, why have other orogenies, occurring on other continents, not shown

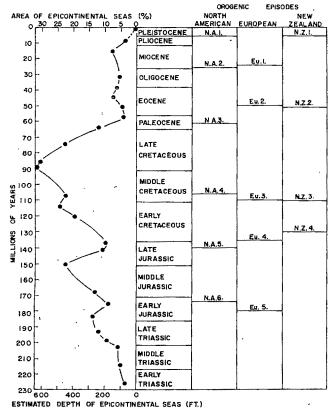

Fig. 3. Depth of epicontinental seas and orogenic episodes for North America.

up on our curve? If orogenies in other continents were coincident with the North American orogenies, the oscillations would be amplified and would result in large regressions and consequent transgressions. Non-coincident orogenies would cause frequent oscillations of small. amplitude and could scarcely be distinguished.

The idea of world-wide orogenic episodes has been hotly discussed for many years. Stille was probably the first to suggest it and there have been many staunch supporters^{3,10,11} and highly respectable sceptics¹². The chief European^{13,14} and New Zealand¹⁵⁻¹⁷ orogenies have been listed with the North American orogenic phases of Damon and Mauger⁵. Since the Triassic, the chief events, although not synchronous, are closely coincident and it is conceivable that the combined result of these orogenies would give a curve of the form shown. It is believed that the curve suggests world-wide orogenic phases which occurred approximately 25, 55, 108, 138 and 175×10^6 yr

The rapid and considerable regression of late Cretaceous time is of interest. Damon and Mauger⁵ have plotted the depth of the Pacific Ocean since late Cretaceous time and a slow, gradual subsidence until the present time is They suggest that this was the cause of the regression, although the sea, in fact, had retreated almost to its present position by middle Palaeocene times. Hallam' has calculated that this subsidence would have caused a eustatic fall of about 40 m, while a 200 m fall is indicated.

According to the theory of continental drift, the Himalayas were formed by the collision of the sub-continent of India and the southern shelf of Asia18. On this theory, a decrease in continental areas and thus a sudden retreat of the seas would result. Using Dietz's2 estimate of the area of the doubly thick continent of 2.44 × 106 km², and of 311×10^6 km² for the area of the present seas, a drop in sea level close to 100 ft. would be expected. would have occurred approximately $60 \times 10^{\frac{1}{6}}$ yr ago¹⁸ and fits in well with the sea level curve.

In summary, I believe that an orogenic event is necessarily associated with a eustatic fall of sea level and that the depth of the epicontinental seas is a sensitive indicator of these events. Using the data from the North American continent, I think that closely coincident world-wide orogenies have occurred since the Triassic and that the principal retreat of the Cretaceous seas is in part the result of the collision of India and Asia which occurred about this time.

I thank Dr C. T. Harper for many useful discussions and Professor J. T. Wilson for reviewing the manuscript.

Fractionation of Iron in the Solar System

Harris and Tozer¹ have recently suggested that magnetostatic attraction between cosmic iron particles is responsible for the observed variation in iron abundance between the inner and outer planets of the solar system. I should like to point out that a crucial assumption in this model is "the uniform single-domain nature" of iron particles in the size range 10⁻¹–10⁻³ cm. The calculations which follow show that iron particles of only a limited size range can take part in magnetostatic accretion.

At room temperature, 300° K, iron is superparamagnetic2 below the critical size of 125 Å. This implies that such particles have no net magnetic moment because of thermal fluctuations. Above that diameter, iron is definitely a single domain but the critical diameter for the onset of multidomain behaviour is very close, 150 Å. As Table 1 shows, at 950° K, the temperature of accretion considered by Harris and Tozer, the superparamagnetic critical size is raised to 184 Å and an upper limit of 3300 Å emerges for the multidomain behaviour. This upper limit comes from the well known fact that a single-domain particle has to be smaller than the domain wall width at the temperature being considered. The width of 3300 A at 950° K is derived from the data given by Kittel³. sizes considered by Harris and Tozer, 10-4-10-3 cm, are far larger than the ones shown in Table I, and thus will have to be multidomained.

> Table 1. CRITICAL SIZES FOR IRON PARTICLES Temperature Superparamagnetic critical diameter $300^{\circ} \, \mathrm{K}$ 125 Å 150 Å 150 Å

Why is it so important for the particles to be single-domained? Because, for a multidomain particle of iron tumbling in a maximum field of 100γ (10^{-3} oersteds), the net moment would be negligible. The value used by Harris and Tozer is 200 gauss, but the real moment could not be greater than a hundredth of this. Because the product of the moments is responsible for the attractive force, the magnetostatic attraction for 10^{-4} cm particles could be a ten thousandth of what Harris and Tozer have assumed. The influence of magnetism on the gravitational attraction will indeed be there but it will be too small to cause an effective change in the capture cross-section.

It might be argued that at some time in the past the particles could have gone through an intense magnetic field emanating from the Sun, and this could have saturated the 10^{-4} – 10^{-3} em particles. But even so, for a sphere of iron of which the crystalline anisotropy energy at 950° K is low (about 10^4 ergs/cm³) and the demagnetizing factor is so large, this saturation moment would be very unstable with time, instantly decreasing to the steady state remanence of about a tenth or a hundredth of one gauss, as discussed before.

My conclusion therefore is that, although the mechanism suggested by Harris and Tozer is ingenious and interesting, it is of little importance for the size of particles they have discussed. In order to be effective, the particles have to fall in a very limited range of sizes as shown in Table 1. It may be possible to postulate that the original particles were indeed in this critical range because of some vagary of cosmology and that the observed particle sizes are larger because of grain growth on sintering.

Banded Flints

Banded flints have long been known to occur in small numbers together with ordinary flints, which are the nodules of chalcedonic silica found in the chalk (Upper Cretaceous) of England and elsewhere. The bands may be observed on fractured surfaces and show up as a variation in colour within the normal colour range of unbanded flints. The exterior of the affected nodule may be ridged in a pattern conformable to the banding.

Formerly, authors, such as Woodward¹ and Sollas², explained the banding as being caused by some kind of infiltration, as would be ascribed nowadays to a natural chromatographic process. Geinitz³ suggested rhythmic precipitation and Gebhardt⁴ regarded a particular example as a test case in the recognition of Liesegang's rings as a natural phenomenon. Cayeux⁵ figured a similar specimen and noted that the effect, silex zonaire, involved the normal constituents of flint only, but he was unable to suggest any cause.

That these bands follow the patterns formed in experimental stress analysis does not seem to have been previously noted. Such stress patterns may be preserved by the "freezing" of an elastic component in a medium which is only plastic during loading. Synthetic resins, which provide both components, were discovered in 1935, and have since been used experimentally. Comparison leaves no doubt that banded flints have been subjected to stresses, probably through collision with other flints.

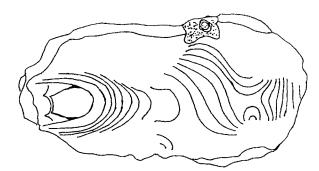

Fig. 1. A sketch of a banded flint. This banded flint is from the collection of Dr W. Hunter, at the University of Glasgow. It is specimen M 1177 in the Hunterian Museum (Geology).

The specimen illustrated in Fig. 1 shows one half of a flint from the collection of Dr William Hunter at the University of Glasgow. The pattern is in black, white, red and yellow according to the amount of compression and subsequent iron-staining. The source of the banded flint is not given but is presumed to be from the oolitic iron-ores of Baden, West Germany, a commercial source for so-called "red Egyptian Jasper", in the eighteenth century. I was privileged to examine Dr Hunter's collection in 1963. A recent article recorded the development of preferred orientation of quartz during recrystallization of flint in conditions of annealing. I suggest here that the naturally banded flints would similarly develop preferred orientation, as a result of the stress "frozen" in the specimen. This is regardless of the demonstration of preferred orientation in a naturally stressed flint, which has not been attempted. The evidence shows that annealing of flint results in preferred orientation which cannot be considered as free from stress, although Green, in the conclusion to his paper, suggests the contrary. An anomaly is thus explained.

PHYSICS

Correction for Atmospheric Refraction in Surveying and Alignment

DETERMINING precisely the direction in which a given point lies is a fundamental problem in surveying and alignment measurements. Optical methods are known which are in principle sufficiently accurate for all practical requirements, but in practice their accuracy is reduced by the effects of the intervening atmosphere.

Refraction by the atmosphere can be considered in terms of its short-period or long-period effects. former may spoil the image or cause it to move about irregularly, which is inconvenient, but can be countered by averaging the readings over a sufficiently long period The measurement is reduced in sensitivity but no systematic error is introduced. The long-period, or quasi-static, refraction cannot even be detected as a rule, and may introduce a completely unrecognized error; it is therefore more dangerous than the shortperiod effect. It is well known, however, that it is possible in principle to recognize and measure this error by the variation with wavelength in the apparent direction of the point due to the dispersion of air.

This dispersion can be measured (inversely) by the V-value for air, defined as is usual for optical materials. The value of V changes only slightly with the physical state of the air, within the usual meteorological range, so it is not necessary to measure temperature, pressure or composition down the light path in order to obtain a reduction of the error to a few per cent of its uncorrected value. V has a value of the order of 110, however, so the difference in direction to be measured is very small. For a refractive error of a few seconds of arc, the difference of angle between red and blue rays must be measured to a few thousandths of a second to reduce the error by 90 per cent. Consequently, separate measurements in red and blue light seem unpromising.

This small value of the dispersion has, however, one beneficial effect: it means that, even over a long range, the red and blue rays nearly coincide over the light path. Thus, for a range of 10 km and a refraction of 20 sec, the maximum distance between red and blue rays is only about 0.3 cm. The rays will be affected by shortperiod refraction to about the same extent. This fact suggests that a differential method of measuring the angle for the red and blue rays should be practicable, and, if so, should be much more satisfactory than separate measurements.

A suitable way of doing this is as follows. Assume the distant point to be represented by a small light source. An image of this is formed by a telescopic system in the plane of a rotating chopper disk with fine opaque and transparent radial bars. The transmitted light is separated into red and blue components by a dichroic beam-splitter, the two components being received by two photo-multipliers. An approximately sinusoidal output is given by each photomultiplier. If appreciable refraction is present,

the image is drawn out into a short spectrum, and the red light is chopped at a different instant from the blue light; thus a phase difference appears between the outputs which can be read on a suitable phase meter. An optical compensator (which may be, for example, a tiltable glass plate placed in the converging beam) can be used to compensate the atmospheric dispersion, compensation being indicated by the phase difference falling to zero. The compensator scale will then give a measure of the dispersion and, thus, the atmospheric refraction. If the equivalent V-value of the compensator is made equal to that of air, the position of the image will, when compensation is effected, be the same as it would be in the absence of an atmosphere.

The chopping frequency is chosen to be much higher (some kc/s) than the important frequencies in the spectrum of atmospheric turbulence. Turbulence will then tend to make both images move together, which will not affect the observed phase difference.

This system has been tested as a bench apparatus, and, although certain practical problems remain to be solved, the results indicate that the precision will be adequate over ranges of interest to surveyors.

The limiting feature is the attainable signal-to-noise ratio. This would be greatly eased if a laser were available (of sufficient ruggedness, portability and cheapness) which emitted red and blue beams simultaneously. Using a thermal light-source and far from optimum components, the results indicate that an error of refraction of one second would be readily observable at a range of 10 km in clear conditions, using an integrating time of about

Solvated Electron Spectrum in Irradiated Ice

RECENT pulse radiolytic studies on transparent samples of ice have demonstrated the existence of three transient optical absorptions which have been assigned to the solvated electron^{1,2}, e_{\varepsilon}, the hydroxyl radical², OH·, and the hydroperoxy radical², HO₂. Particular attention has been paid to the influence of temperature on their spectral, yield and kinetic characteristics. For e-, as the temperature is decreased, λ_{max} shifts to shorter wavelengths, the yield decreases, and the lifetime increases. These observations indicated that an ice sample highly irradiated with $^{60}\mathrm{Co}$ gamma-rays at 77° K might show a stable, low yield es having an absorption maximum at about 6300 Å.

In order to test this hypothesis, experiments were carried out in the following way. A cylindrical ice sample (20 mm in diameter and 25 mm in length), which had been grown by slowly lowering a sealed test tube containing degassed, triply distilled water into a cooling bath at -5° C, was fixed with a thermocouple, cooled to 77° K by slowly lowering it into a Dewar containing liquid nitrogen, and irradiated in a 1.7 Mrad/h source. sample was then transferred to a specially designed quartz Dewar attached to a Cary spectrophotometer, and the spectrum was recorded. One additional experiment was carried out in which oxygen was completely excluded from the irradiated system, and it gave similar results.

A typical result is shown in Fig. 1. A maximum appears at 6400 ± 100 Å (other very strong absorptions in the ultraviolet have been omitted2). The yield of this absorption increases with dose up to about 5 Mrads and then approaches a plateau value. Based on the linear portion of the yield-dose plot and $\varepsilon_{\rm max} = 1.7 \times 10^4 \, \rm M^{-1} \, cm^{-1}$ (refs. 3–5),

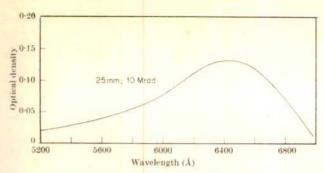

Fig. 1. Spectrum of solvated electron in ice at 77° K. Total dose; 10 Mrads

a G-value of 2×10^{-4} is estimated. Although the absorption appears to be thermally stable at 77° K, it can be photobleached with visible light. The absorption disappeared, however, when the sample was warmed to 112° K.

The fact that a stable solvated electron absorbing below 7000 Å can be formed in ice has relevance for various theories related to the formation, structure and decay of this entity in other media such as liquid water and alkaline ice glasses.

insulated brass "tuning fork", the assembly being mounted in a transparent plastic tank, capacity 2 l. The cathode was held 2.5 cm below the liquid surface and the electrodes connected to a constant current source which gave a cathode current density of 0.125 amp/cm2. The bubbles were photographed using flash illumination. The sizes of the bubbles were obtained by measuring their diameters on an enlarged projection of the photographic negative. Extremes in bubble sizes were ± 15 per cent for bubbles having diameters of the order 0.0025 cm and ±33 per cent for diameters of the order 0-0075 cm. Reagent grade chemicals and tap water were used.

The dramatic effect on bubble size of added solute can be seen in Fig. 1, the addition of 1 molar sodium bromide markedly decreasing, and addition of 1 molar ammonium bromide markedly increasing, the size of the bubbles relative to the size of bubbles in water under the same conditions. These trends can result from a sensitivity of the bubble size to water-solute interaction within the aqueous solution. This hypothesis was tested by monitoring the variation in mean bubble diameter with increasing concentrations of t-butyl alcohol in water, as shown in

Mixtures of water and t-butyl alcohol display marked extremes, both with regard to their own properties6 and those of solutes in their solvent systems7,8, as the concentration of alcohol is varied. These effects reflect the changes which occur in the structure of the aqueous mixture, as a consequence of the varying demands of water-water, water-alcohol and alcohol-alcohol interactions.

At low t-butyl alcohol mole fractions, $x_2 < 0.02$, the bubble surface area (calculated from the mean diameters) is greater than in water (Fig. 1), the surface area decreasing with the increasing mole fraction of alcohol. In these dilute solutions, the consequence of forming a rapidly expanding bubble together with a slow rate of diffusion of the alcohol solute to the bubble/liquid interface means that the hydrogen bubble is in an extreme non-equilibrium The diffusion rate, however, increases with in-

Effect of Added Solutes on the Size of Hydrogen Bubbles liberated from a Cathodic Wire in Aqueous Solution

An important tool in fluid flow research is flow visualization using the hydrogen bubble technique. Here a wire cathode is mounted normal to the water flow and connected to an electrical pulse generator. The planes of hydrogen bubbles, which evolved from the wire, follow the velocity variations in the flow^{1,2}. The patterns formed by the hydrogen bubbles may be photographed and the velocity profile analysed. In order to use this technique to full advantage the size of the bubbles must be sufficiently small for them to remain in the same velocity profile but sufficiently large for observation.

It has been generally assumed that the size of bubbles released in aqueous solutions is unaffected by added solutes, added salts merely operating to enhance the conductivity of water, thereby facilitating electrolysis. It has been established3-5, however, that the bubble size depends on the interfacial contact angle between the cathode and the liquid and on the polarization of the cathode. In the course of a detailed investigation into flow visualization, we investigated the size of bubbles released from a wire in various aqueous solutions in static conditions and we now briefly report evidence to show that the size of a hydrogen bubble released from a wire cathode in aqueous solutions can be particularly sensitive to the nature and concentration of added solutes.

A stainless steel wire cathode, length 5 cm and diameter 0.05 mm, was supported between two prongs of an

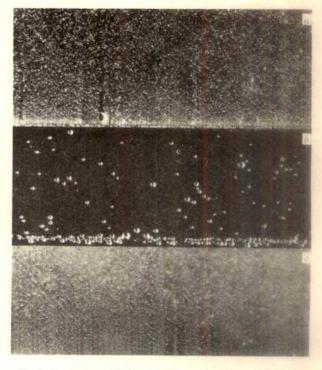

Fig. 1. Comparison of the sizes of bubbles released from a stainless steel cathode having diameter 0-05 mm with current density 0-125 amp/cm-immersed, at 25°C, in (a) water, (b) 1 molar aqueous solution of ammonium bromide, and (c) 1 molar aqueous solution of sodium bromide.

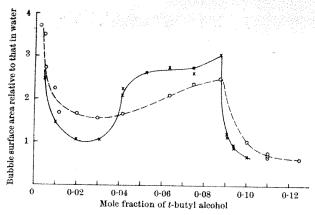

Fig. 2. Surface area of hydrogen bubbles (computed from mean bubble diameter) relative to those in water under the same conditions as given in Fig. 1 in mixtures of t-butyl alcohol and water, x_2 being mole fraction of alcohol. Data refer to two independent series of measurements.

creases in the alcohol mole fraction and therefore the bubble surface area diminishes. At alcohol concentration greater than $x_2 = 0.02$, the surface area increases (compare with the solution containing ammonium bromide) reaching a maximum in the $x_2 = 0.08$ region, and then decreases rather sharply. This type of behaviour is comparable with the sound absorption properties of such mixtures. Indeed, both sound absorption properties and the spectra of solutes in these mixtures show that in this concentration region the structure of the essentially water dominated solution breaks down, the system having maximum disorder in the $x_2 = 0.09$ to 0.1 region. Although the required water/steel surface tension and contact angle data are not available for this system, the contact angles for mixtures of ethanol and water on a copper surface10 undergo dramatic changes in a comparable concentration range.

With increases in temperature the bubble size in water steadily decreases, and this trend is comparable with the effect of added potassium chloride to water at a given temperature. This pattern of behaviour is in general agreement with the currently accepted ideas concerning the breaking action of most alkali halides on the structure^{11,12}. For example, a decrease in bubble size is also effected by the addition of 1 mole of sodium chloride, bromide, iodide and sulphate.

Relationships between the Masses of Subatomic Particles

In a previous communication¹, the bound rest mass of the proposed tamaid particle, t_0 , was calculated from available experimental data² to be equivalent to 25.95 MeV. The subatomic particles of zero charge have been shown to fall into a quantized series obeying the relationship

Mass of subatomic particle = M = 25.95 n + 134.97

Here n is an integral quantum number and the constant term is the mass of the π^0 meson. From a consideration of the available numerical data the possible existence is now postulated of another mass-energy entity, b, which, in association with the tamaid, could be employed to build up units of matter which correspond to all the known muons, mesons, baryons, etc. It is proposed to call this subsidiary entity a "bach" (Welsh—the little one), and present calculations suggest that it has a bound rest mass corresponding to b = 0.3263 MeV. It is therefore smaller than the electron (e $^- = 0.511 \text{ MeV}$) and must be associated with a larger De Broglie wavelength.

If the bachs and tamaids really constitute the ultimate particles of matter out of which all the other mass-energy states may be created, it is necessary to assume that all subatomic particles consist essentially of a core of tamaids associated with a mass-energy aura, or field, of bachs whose physical form of natural existence is not easy to visualize.

Equation (1) deals with particles which are heavier than the π^0 meson. It is now proposed to extend this theory to include the muons, and it will therefore be convenient to replace the quantum number n^1 by a new integral function x defined by

Number of tamaids =
$$x = (n + 5)$$
 (2)

The number 5 represents the number of tamaid particles which aggregate to form the core of the π^0 meson, and, as will be shown later, these must be associated with 16 bach entities, that is y = 16. The term y is a secondary quantum number which, for uncharged subatomic particles, may be defined by

Number of bachs =
$$y$$
 (3)

To derive the final equation (4) it has also been necessary to postulate the existence of a further quantum number zwhich can have any of the integral values, z = 0, 1, 2, 3, etc., and which is mathematically related to x and y by the fundamental expression.

Total number of tamaids and bachs in a subatomic particle = (x + y) = x + (3 + 13z)

Because the masses of t_0 and b have been derived earlier it is now possible from equation (4) to compute the masses of the uncharged subatomic particles, and the results are shown in Table 1. In this series, z has the value 0 or 1, and is undoubtedly concerned with some internal "energy level" system.

$$M = \text{mass of a subatomic particle} = 25.95 \ x + 0.3263 \ y$$

= $xt_0 + yb$ (5)

The binding energy of each individual tamaid in the central core of the subatomic particle must be particularly constant or equation (5) would not be expected to hold with any degree of exactness.

For the main uncharged series, z = 1 and y has the constant value of 16, that is (3 + 13). It would seem that this value of y is absolutely essential for the stability and natural existence of uncharged members of the series. If z = 0, we have from equation (4) the condition y = 3which is unacceptable, and y will have to increase by 13 units, that is to y = (3 + 13), before we can expect to find further stable subatomic particles. confirms this reasoning, for no particles are recorded in the range x = 6 to x = 18. When x = 19 tamaids, these

associate with the dominant parameter, y=16 bachs, to give the K⁰ meson (497.82 MeV), z again being taken as equal to unity. The series then builds up again in a stable fashion with y=16, z=1, and x increasing from 19 to 90 in an integral manner.

The problem of calculating the masses of charged subatomic particles is usually complicated by a lack of understanding of the fundamental relationships between mass and electrostatic charge. Curiously enough, these difficulties do not seem to militate against the direct application of the present theory to the computation of the masses of charged muons, baryons, etc. Equation (4) must be slightly modified for charged particles and is written in the form

Number of particles = (x + y) = 6 + (3 + 13z) (6)

where z can have any of the integral values 0, 1, 2, 3, etc. The phrase "Number of particles" in equation (6) has been used deliberately because while in equation (4) there seems to be a definite mathematical segregation of the x tamaids from the y bachs, this condition does not apply to equation (6). Indeed, the dominant parameter appears to be the summated integral number (x + y), irrespective of the types of particles concerned. This

number also determines the value of z, that is $z = \frac{x+y-9}{13}$.

Stable structures are only achieved by the successive addition of packets of thirteen particles. Table 2 gives the data for the known charged subatomic particles. When z=0, stable particles exist for the corresponding condition (x+y)=9, and these are the muons μ^+ μ^- , respectively, with values of z=0. The π^+ meson will be seen to be associated with 30 bach particles and to have z=2.

Following these, we again have the intrusion of the "magic number", 13, and no stable subatomic particles are experimentally observed until we reach the x^+ meson with (x + y) = 22 and z = 1. Obviously from equation (6) y can only have the value 16, as is the case for the uncharged particle, if x = 6 and z = 1. For any other values of y, the particles are charged.

It should be noted that although stability laws preclude the existence of an uncharged particle having x=6, the related charged particle would have (x+y)=9, which is a condition of stability under the conditions of equation (6). This particle has not been experimentally detected but its theoretical mass would obviously be 156-68 MeV.

Because the rest mass values of the tamaid and bach used in this paper are only average values computed from the better established masses of the subatomic particles, the agreement of experimental and calculated values over this wide range of masses seems to be encouraging support for the present theory. The calculated value for the Σ^+ baryon is slightly high, but the experimental value for Σ^- is 1,197·33 MeV, which is in good agreement. Values for the negatively charged subatomic particles can be derived in a similar manner.

The chief quantum rules which seem to ensure the stability of the subatomic particles may be summarized as follows. (a) The cores of uncharged particles build up in single tamaid units. When equation (4) applies and y = sixteen bachs, the subatomic particles are uncharged. (b) The cores of charged subatomic particles contain up to six tamaids. When equation (6) applies it must be assumed that the remaining (x - 6) tamaids have linked up with the corresponding y bachs in the quantized stationary states and that the total particles in these states, regardless of differing rest-masses, obey the normal rule, that is

Particles external to the core = (x-6) + y = (3+13z) (7)

This latter equation is identical with equation (6).

One is tempted to visualize the bachs as rotating in orbits around the tamaid cores because equation (4) is very reminiscent of the classical Bohr-Bury theory of atoms, and suggests a solid core of x tamaids surrounded by $y = (3+13 \ z)$ bachs forming orbital shells of the type 3, 13, 13, 13, etc., in conformity with the quantum numbers z = 0, 1, 2, 3, etc. Equation (7) follows the general pattern, but one would expect some discontinuity in the unique case when x = 6 and this behaviour is demonstrated in Tables 1 and 2.

These equations indicate very clearly how uncharged particles differ from charged particles and offer convincing reasons why the neutron should be heavier than the positive proton whereas it is well known that the positive π^+ meson is heavier than its neutral counterpart π^0 . The difference is essentially a result of the varying bach content of the sister particles which nevertheless have the same overall tamaid content, that is, identical x values. If the wave mechanical concepts of Schroedinger are to be applied to this present theory, the existence of some form of attractive force between particles will need to be postulated which would be in equilibrium with the centrifugal forces produced in orbital states. In the present case, the calculations would also have to take into account the existence of two types of particle external to the tamaid core. During this work some relationship was sought between the mass of the electron $(m_e = 0.511 \text{ MeV})$ and

the bach and it was empirically noted that $\frac{4}{5}b = m_e^2$.

It is very singular that the fundamental parameters which seem to determine whether subatomic particles are charged or uncharged are directly associated with a series of quantum numbers which have been employed in calculations involving small quantities of matter only, that is, with the inclusion of no specific electrostatic quantum number or function, for example, hypercharge. The semi-empirical equations given in this paper certainly suggest that electrostatic charge and mass may be merely uniquely created forms of some primigenous material and the exact mathematical elucidation of the relationship between these two quantities would be of the greatest fundamental importance.

It should be possible by means of the present theory to predict the probable nature of the collisional event in a hydrogen bubble chamber provided it is accepted that the accelerator beam is able to yield extra packets of mass-energy, E, to provide the bachs necessary to yield stable systems. Consider the case of an accelerated K⁻meson, $(19t_0 + 3b)$, impacting on a proton, $(36t_0 + 12b)$, and yielding a collisional chaos $(55t_0 + 15b)$, plus energy = E. This chaos could degrade to an energetic proton, $(36t_0 + 12b)$, and a π^- meson, $(5t_0 + 30b)$, or to unstable tamaid system, $(19t_0)$, which absorbs further energy to form a stable K⁰ meson $(19t_0 + 16b)$. The K⁰ meson could then decay to yield a π^+ meson and a π^- meson, both being $(5t_0 + 30b)$.

both being $(5t_0 + 30b)$.

These mesons finally degrade to muons $(4t_0 + 5b)$, surplus energy being lost to the ambient medium.

The ultimate nature of the bach remains speculative, but it is for serious consideration whether it is in any way associated with the muonic neutrino.

Surface Topography of Non-optical Surfaces by Projected Interference Fringes

In the light slit microscope of Schmaltz¹ a narrow slit of light is projected obliquely onto an irregular surface, and the trace of the slit, viewed normally through a microscope, provides a section of the surface to a scale depending on the angle of incidence of the light. This technique has the disadvantages that (a) there is only a single slitimage, which must therefore be made to traverse the surface, and (b) there is very little focal depth in the slit image if it is made narrow enough. If the width of the slit is to be d it must be projected with numerical aperture $\alpha = \lambda/d$ and the focal depth is approximately λ/α^2 , where λ is the wavelength of the light.

These difficulties can be overcome by projecting onto the specimen a set of interference fringes produced by two collimated coherent pencils of light intersecting at an angle; the bright and dark fringes form in planes parallel to the bisector of the angle θ between the pencils and

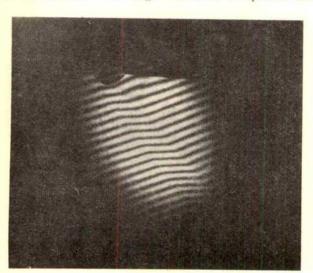

Fig. 1. Fringes with 3 mm spacing on a ridged card.

it can easily be shown that the fringe spacing, σ , in a plane making an angle β with the bisector, is given by

$$\sigma = \frac{\lambda}{2\sin\frac{\theta}{2}\sin\beta}$$

Thus fringes with any spacing down to say 0.7λ , corresponding to $\theta = \beta = 90^{\circ}$, can be produced and used to intersect the surface to be inspected. This technique is, of course, only practicable using a laser as a high intensity coherent source.

THE SOLID STATE

Permanent Magnet Properties

The claim by McCurrie¹ for a $(BH)_{\rm max}$ value higher than previously recorded is manifestly incorrect, although the values he quotes from other publications are probably correct. For a permanent magnet material with remanence B_r in gauss, the theoretically highest possible $(BH)_{\rm max}$ value in gauss-oersteds is $\frac{1}{4}B_r^2$; this limit is on the basis of no change in the intrinsic magnetization between B_r and the $(BH)_{\rm max}$ point. In practice, some high coercivity materials approach this limit fairly closely, as illustrated

		Table 1	
Source	Be	$\frac{1}{4}B\tau^2$	$(BH)_{\max}$
Walmer ²	6,450 gauss	10.4×10^{6}	9.5×10^{8} gauss-oersteds
Chaston ³	7,125 gauss	12.7×10^{s}	10.3 × 10° gauss-oersteds
McCurrie ¹ (a)	5,280 gauss	$7 \cdot 0 \times 10^{s}$	14-1 × 10° gauss-oersteds
McCurrie (b)	6,065 gauss	9.2×10^{6}	11.0 × 10° gauss-cersteds
McCurrie (c)	4.050 gauss	$4 \cdot 1 \times 10^{6}$	6.9 × 10° gauss-cersteds

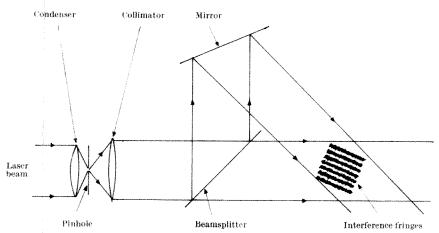

Fig. 5. Method of forming closely spaced fringes by means of a beamsplitter.

Figure 1 shows fringes at a spacing of 3 mm projected onto a card which has a ridge with an adjacent furrow, both of angle 125°. Figure 2 shows an aluminized ground glass surface, with fringe spacing of 18µ, viewed through a 0·15 N.A. microscope objective; the surface contains a ridge of angle 125°. Figure 3 shows 18µ spacing fringes on a portion of an oak leaf on the reverse of a 1966 sixpence, a metal surface with a fairly high polish. The photographs were taken with light of wavelength 6328 Å from a helium-neon laser.

The fringes can, of course, be produced by any of a number of well known methods; Fig. 4 shows a Wollaston prism arrangement suitable for large fringe spacings, while Fig. 5 depicts an arrangement of a beamsplitter and a mirror which could be used for large angles, θ , and small fringe spacings. The fringes produced by either of these methods can be observed on surfaces of widely differing optical properties, for example, polished metal, ground glass or wood.

An obvious modification is to project the same fringe system through a beamsplitter onto two nominally identical objects; if these are viewed from an appropriate angle the two fringe systems will produce a moiré pattern indicating the differences between the objects.

We are grateful to Mr J. H. Toyer for help in preparing the specimens.

by the test values of Walmer² and Chaston³ which are quoted by McCurrie, but his own tests grossly exceed this limit, as shown in Table 1.

It seems probable that McCurrie's reported $(BH)_{\rm max}$ values are in fact $(4\pi JH)_{\rm max}$.

 $(BH)_{
m max}$ has for many years been the accepted criterion of merit for permanent magnet materials, because it is a measure of the external magnetic energy available in static operation, but for dynamic operation other criteria apply, and there may then be merit in the value of $(4\pi JH)_{
m max}$.

CHEMISTRY

Exothermic Reactions behind a Reflected Shock

THE use of reflected shock waves to initiate exothermic reactions in a shock tube is commonly concerned with the ignition of oxygen and simple fuel molecules. The speed of the incident shock, U_s , determines the speed of the reflected shock, U_r , and the temperature, T_s , at which the reaction takes place. If T_s is sufficiently high, an explosion

occurs almost instantaneously and the reflected shock leaves the end plate at high speed because of the release of the energy of combustion. At lower temperatures there is an induction period, τ , before reaction occurs; a combustion-driven wave then sets out after the slower non-reactive reflected shock and eventually the two waves coalesce. The use of large windows near the end plate of the shock tube has permitted streak photography of this phenomenon for carbon monoxide-oxygen and hydrogenoxygen-argon² mixtures. A typical record is depicted in Fig. 1.

We have written a computer programme which, for a given value of U_s , calculates the value of U_r when there is no reaction behind the reflected shock $(R^*, \text{ Fig. 2})$ and also when reactants pass instantly to equilibrium products behind this shock $(D^*, \text{Fig. 2})$. The programme does not cater for undiluted fuel-oxidant mixtures but can accommodate the heat release from mixtures diluted with argon (≥ 80 per cent).

It is not possible to install large windows in our shock tube (5 \times 3 in.) in order to measure U_r from x-t photographs. The gold film detectors used to measure U_s . however, can also be used to measure U_r . For this purpose binary circuits are required to protect the triggers of the microsecond counter so that the incident shock is ignored. Although the positions of the detectors are fixed in the shock tube, attachment of a plug to the end plate allows U_r to be determined after the shock has travelled different

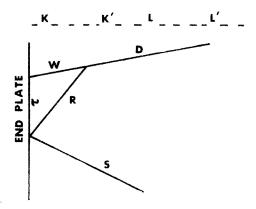

Fig. 1. A diagram of wavefronts at the end of a shock tube when there is an ignition delay after shock wave reflexion. S, Incident shock; R, reflected shock; W, reaction shock; D, combustion-driven wave. K, L are detector stations which become K'. L' when the end plug is removed.

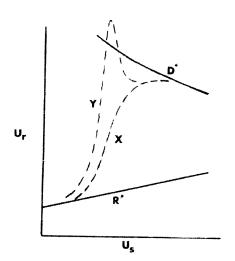

Fig. 2. Plots of reflected shock speed against incident shock speed, R^* , Computed for no reaction behind the reflected shock; D^* , computed for complete reaction behind the reflected shock; X, reflected shock travels about 1.0 in. before timed; Y, reflected shock travels about 3.5 in. before timed.

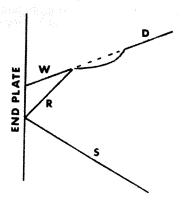

Fig. 3. A diagram of wavefronts required to explain abnormally high reflected shock speeds.

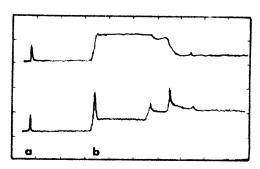

Fig. 4. Oscilloscope traces depicting induction periods in a methane-nitrous oxide-argon mixture (20 μ sec/cm). Upper trace, absorption by nitrous oxide at 2590 Å; lower trace, absorption by OH at 3670 Å. a, Incident shock; b, reflected shock.

distances from the end plate. Results with ammoniaoxygen or nitrous oxide-argon mixtures have been

reported³ and are shown in Fig. 2.

The overshoot of U_r values in plot Y of Fig. 2 cannot be explained by the geometry of Fig. 1. For example, if the end plug is present, timing is between K and L. The timer is started by R and stopped by D and thus U_r is an average of two values, one from plot R^* and one from plot D^* of Fig. 2. At the same U_s value, when the end plug is absent, timing is between K' and L'. The timer is started and stopped by D and the measured U_r falls on plot D^* of Fig. 2. Comparably, for large values of τ , the timer is started and stopped by R and the measured U_r falls on plot R^* . Thus, according to Fig. 1, X and Y plots of Fig. 2 must lie on, or between, the R^* and D^*

Thus when overshoot is detected, W and R cannot coalesce instantaneously to yield D but, for a short interval of time, there must be a wavefront the speed of which is faster than that of D. This wave lacks the support of energy available from complete combustion of the reactant mixture and must decelerate. In doing so it becomes D. Figure 3 should depict the true state of affairs. Thus, under certain circumstances, one may be able to detect two wavefronts at the end of the induction period. The first of these fronts can only permit partial conversion of reactant to equilibrium products.

The windows in our shock tube are 14 mm from the end plate and a slit system defines a 1 mm beam of light from a xenon lamp. After leaving the tube the beam divides so that absorption can be monitored simultaneously on two monochromators set at different wavelengths. A record obtained with a mixture of methane-nitrous oxide-argon (6 per cent: 24 per cent: 70 per cent) is shown in Fig. 4.

Runs with previously examined mixtures confirm that it is possible to detect two wavefronts at the end of the induction period in the systems hydrogen-oxygen, carbon monoxide-oxygen, hydrogen-nitrous oxide, ammoniaoxygen and ammonia-nitrous oxide (plus argon, ≥70 per cent). In all cases τ was short, about 50 µsec or less. At lower temperatures, and thus at larger τ values, only one front was detected at the end of the induction period. The critical conditions for detecting two wavefronts depend on the distance separating the optical path from the end plate, the fuel-oxidant ratio, the argon concentration and the reactant pressure.

The energy release in the first wave can vary and may be small enough to make detection of the front quite a difficult matter. The investigation of this phenomenon is suggested to those who have the facility of taking streak

photographs at the end of a shock tube. I thank Dr C. L. Cook for his interest.

Laser Raman Spectra of Sorbed Species Physical Adsorption on Silica Gel

THE principal method of studying the bonding characteristics of adsorbed species is to use infrared vibrational spectroscopy. Although the method has been applied to an extensive range of adsorbates and substrates, the technique suffers from the problem that, because of substrate adsorption, only high frequency modes of vibration of the adsorbate can be detected. The Raman effect would seem to offer an alternative method of study.

The Raman spectra of organic molecules adsorbed on silica gel were reported some years ago by Karagounis and Issa¹, who used the Brandmüller method² for crystalline powders, which they adapted to obtain spectra of adsorbed species under very specific conditions of sample thickness. We wish to report spectra obtained very conveniently on a conventional laser Raman spectrometer, using the machine in an unmodified form.

The adsorbant was contained in a 'Pyrex' cell fitted with an optical flat at one end and a tap, for connecting to a vacuum line, at the other. The spectra were obtained on a standard Cary 81 laser Raman spectrometer, the end window of the cell being placed in good optical contact with the hemispherical lens of the instrument. It was found that the quality of the spectra depended on the size of the adsorbent particles. Initial experiments were carried out on a 100-200 mesh silica gel, because this was known to have a very high surface area and thus potentially a large number of molecules in the volume examined by the spectrometer. This, however, gave rise to a very high background, a high noise level and spurious bands. These latter disturbances came from the high mobility of the fine particles of gel in the small sampling area of the instrument which resulted in the appearance of a band whenever a gel particle moved across the illuminated volume. The size of the adsorbent particles was therefore increased to 18-30 mesh to reduce these effects but at the expense of a loss in surface area. The silica gel in these experiments was standard chromatographic grade, cleaned

by heating to 150° C in vacuo for 12 h. After this time the pressure had fallen to below 10-4 torr.

The materials studied were carbon tetrachloride. bromine, carbon disulphide and trans-dichloroethylene on

silica gel.

The gel alone produced a relatively weak emission near 185 cm⁻¹, a strong band near 235 cm⁻¹ and a very broad weak band in the region from 300 to 500 cm⁻¹. The second of these bands may, however, have been a spurious line characteristic of the instrument³. Apart from these, the spectrum was remarkably unobstructed. spectra are shown in Fig. 1.

Carbon tetrachloride/silica gel was examined over a wide pressure range. The monolayer capacity of the gel in this system was estimated using the Brunauer-Emmett-Teller method and 0.218 g of carbon tetrachloride/g of gel was added, being equivalent to a surface area o 174 m²/g. It was assumed that the area of the carbon tetrachloride molecule approximates to 18.6 Å2. Spectra were obtained at less than monolayer coverage and at heavier adsorption. No observable difference was found between the spectra except for their intensities. It is thus apparent that adsorption had little effect on the potential energy of the adsorbate molecule, that is the association with the surface was very weak.

The next experiment used bromine as adsorbate. The yellow/orange colour of the system did not prevent spectra being recorded and excellent results were obtained at quite low vapour pressures, certainly down to 0.01 svp at 25° C. As in the previous case the emission occurred at a frequency similar to that in the liquid. In fact, the results were Br_2 (gas) 316·8 cm⁻¹; Br_2 (liquid) 306 cm⁻¹; Br₂/SiO₂ 314 cm⁻¹. It therefore seems that the adsorbed halogen closely resembled the gaseous species. could be interpreted that the adsorbent-bromine association is much weaker than the induced dipole-induced dipole interaction in the liquid. Because of its relatively low boiling point and very low latent heat of vaporization this must in turn be weak.

One of the effects of weak association on vibrational spectra is the distortion of the selection rules. Thus it is characteristic behaviour that in the charge transfer complexes of the halogens the stretching vibration of the homonuclear diatomic is infrared active. Carbon disulphide has three modes of vibration, two of which are Raman inactive. It is noteworthy that these modes (sulphur-carbon-sulphur bending at $397~\mathrm{cm^{-1}}$ and the asymmetric stretching mode at 1,523 cm⁻¹) remained inactive in the adsorbed case. In the other sample where mutual exclusion applies, in trans-dichloroethylene, no bands, normally Raman silent, appeared in the spectra

of the sorbed species.

One possible explanation for these results is that the instrument had simply recorded the spectrum of the vapour of the adsorbate. The high intensity of illumination could well have involved an appreciable rise in temperature and subsequent desorption of the surface layer. The intensity of the Raman bands rules out the proposal for, in the case of carbon tetrachloride, a vapour pressure of some tens of atmospheres would be required to give such prominent Raman bands. As the bulk of the adsorbent is not illuminated, any desorbed vapour would be promptly readsorbed on the "cold" surrounding gel. It is just possible that multiple reflexions within the gel could increase the illumination efficiency to such an extent that vapour at a low pressure could emit strong Raman lines. To check this hypothesis a clean gel was put in a tube filled with nitrogen at the relatively high pressure of 1 atm. No trace of the nitrogen-nitrogen stretching vibration at $\Delta \gamma = 2.331$ cm⁻¹ could be observed. It must therefore be assumed that the spectra did in fact come from adsorbed species.

It is quite clear that the interaction in these four cases must be extremely weak, as shifting in frequency is almost negligible and the selection rules do not break down. Similar results have been reported in the infrared by Sidarov⁴ for some molecules adsorbed onto porous glass. Raman spectroscopy has a great advantage over absorption measurements in that a wide frequency range can be studied easily. At present spectra may be recorded from about $150-3,400 \text{ cm}^{-1}$.

We thank Professor I. R. Beattie for making available the laser Raman facilities, the Science Research Council for providing a grant to purchase the Cary spectrometer and NATO for financial assistance.

Vinyl Alcohol: a Stable Gas Phase Species?

During a study (unpublished results) using a mass spectrometer of the oxidation of dideuteroacetylene at 280° and 330° C in a 'Pyrex' reaction vessel, which had previously been used in the oxidation of acetylene, the products were found to contain a mixture of perdeuterated and monoprotonated acetaldehyde, acetic acid and methanol. Except in the case of methanol, the concentration of the monoprotonated substance was greater in the initial stages, but as the reaction progressed the proportion of the fully deuterated compound increased (Fig. 1) The 4 per cent C2HD impurity cannot account for the hydrogen atoms which must therefore have originated on the walls of the reaction vessel, either as a part of a polymeric substance or in the form of absorbed water. the latter source being favoured because water is an important product of the oxidation and, as the reaction proceeds, \tilde{D}_2O will be absorbed on the walls and cause the increase in the proportion of fully deuterated products. To test this, water was added to the oxidation of dideuteroacetylene and mass numbers 48, corresponding to CD₃CDO+, and 47, corresponding to C₂D₃HO+, were monitored; in accordance with this suggestion, mass number 48 was suppressed while 47 was, at least initially, unaffected (Fig. 2).

Three possible surface reactions can be considered. (a) Acetylene reacts with water on the surface. Although acetylene and water will react to give acetaldehyde on surfaces1, no acetaldehyde was formed during 1 h from a

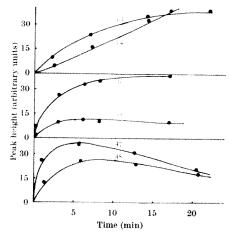

Fig. 1. Formation of isotopically labelled products from the oxidation of C_2D_2 . Temperature, 330° C; pc_2D_3 , 60 mm; po_3 , 100 mm. The mass numbers corresponding to the various curves are given on the diagrams.

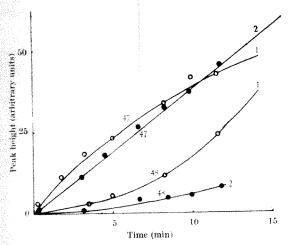

Fig. 2. Effect of the addition of water on the development of mass numbers 47 and 48. Temperature, 280° C; $\mu\text{C}_2\text{D}_2$, 60 mm; μO_2 , 100 mm. Curve 1: no water; curve 2: 20 mm water added.

mixture of acetylene, 100 mm mercury partial pressure, and water, 20 mm mercury partial pressure, at 330° C. (b) Acetaldehyde exchanges with water on the surface. A mixture of acetaldehyde, 100 mm mercury partial pressure, and D₂O, 25 mm mercury partial pressure, was monitored at 280° C for 100 min. Table 1 shows that exchange does take place, but a conversion of less than 10 per cent in this period is too slow to account for our observation.

Tablet

Peak height Mass (arbitrary No. units) at		Chang 45 w	Changei n peak 45 with time		e in peak ith time	Change in peak 30 with time	
45 44 30	zero time 0 52 0	Time (min)	Peak height (arbitrary units)	Time (min)	Peak height (arbitrary units)	Time (min)	Peak height (arbitrary units)
29 16 15	74 0 53	$0\\23.0\\101.5$	0 1·6 5·2	0 20-5 99-0	0 1·5 4·5	$0 \\ 21.5 \\ 100.0$	0 0·1 0·04

The increase in mass number 16 (CDH₂⁺) but not in mass number 30 (CDO⁺) shows that the deuterium atom is incorporated in this methyl group of the acetaldehyde and the most reasonable mechanism for this reaction involves a keto-enol tautomerism (see also ref. 2)

$$\begin{array}{ccc} & & & & \\ & &$$

Mass number 29 (CHO⁺) is unaffected by the reaction. Step (1) must therefore be slow and rate-determining, and step (2) must be rapid, giving a very low stationary concentration of vinyl alcohol. A similar conclusion has been drawn from work on a polar solution³. (c) A precursor of acetaldehyde undergoes exchange during or before conversion to acetaldehyde. It has previously been suggested⁴ that the formation of acetaldehyde in acetylene oxidation is the result of hydrogen abstraction by the radical -CH₂CHO, formed in the sequence

$$C_aH_a + \dot{O}H \longrightarrow H\dot{C} \longrightarrow CH(OH) \longrightarrow C\dot{H}_aCHO$$

If the abstraction reaction occurred only with water absorbed on the vessel surface this would explain our findings but, because 'CH₂CHO is a π -radical, its reaction with oxygen⁵ is likely to be too rapid for it to be the precursor of acetaldehyde in oxygen-rich mixtures. The tautomer, 'DC=CD(OD), from dideuteroacetylene oxidation is, however, a σ -radical with low reactivity towards oxygen⁶ and can abstract a hydrogen atom in the gas phase to give vinyl alcohol which rearranges to acetaldehyde at the walls of the vessel

$$C = C \xrightarrow{D} \xrightarrow{RD} \xrightarrow{D} C = C \xrightarrow{D}$$

The other monoprotonated products (Fig. 1) derive, at least in part, from the further reactions of CHD₂CDO. In Fig. 2 mass number 47 (CHD₂CDO⁴) increases immediately while the rate of production of mass number 48 (CD₃CDO⁺) is autocatalytic, which shows that the formation of D₂O during the oxidation of dideuteroacetylene is necessary for the production of perdeuteroacetaldehyde (this is confirmed by the addition of water). Consequently, none of the vinyl alcohol formed rearranges homogeneously to give acetaldehyde.

Vinyl alcohol is thus capable of a separate existence but tautomerizes rapidly to acetaldehyde whenever the steric and polar conditions are favourable—that is, in a polar solution or on a water coated surface.

Charge Transfer in Mono-hydroxo and Mono-fluoro Complexes of Tripositive Cations in the First Transition Series

Values of ΔG_{ass} (Table 1) have been measured for the reactions

$$M_{\rm aq}^{3+} + L_{\rm aq}^{-} = M L_{\rm aq}^{2+}$$

where L^- is OH⁻ or F⁻ and ML^{2+} are the hydroxyl complexes of the cations Ti^{3+} to Co^{3+} or the fluoride complexes of Fe³⁺ and Cr³⁺. Here a correlation is demonstrated between a function involving $\Delta G_{\rm ass}$ and $\Delta G_{\rm redox}$ for the overall electron-transfer process

$$M_{\alpha}^{*+} + L_{\alpha\alpha}^{-} = M_{\alpha\alpha}^{2+} + L_{\alpha\alpha} \tag{2}$$

which indicates a charge-transfer structure for the associated species, $M^{3+}L^- \leftrightarrow M^{2+}L$.

The original discussion of Wells¹ when he considered the MOH^{2+} contact complexes referred in a general way to the modification of the 3d electron distribution by electron delocalization, but concentrated on specific factors possibly affecting individual enthalpy and entropy changes. Because the separation of $\Delta G_{\rm ass}$ values into enthalpy and entropy terms, besides requiring a constancy of medium for comparability, and in optical measurements a problematical temperature independence of extinction coefficient, involves in addition appreciable or unassessable experimental uncertainty (for example, Co^{3+} and V^{3+} data¹, respectively), only the sequence of stabilities given by $\Delta G_{\rm ass}$ will be considered here. $\Delta G_{\rm ass}$ for MOH^{2+} is obtained from -RT log K-18.78 kcal, the K values being the hydrolysis constants given by Wells¹ and +18.78 kcal is ΔG for the ionization of water² at unit ionic strength.

Values of $\Delta G_{\rm ass}$ for fluoride complexes are usually much less negative than those for hydroxylation. For Fe²⁺ complexes Wells⁹ has suggested either greater covalency in the hydroxylated species or a contact configuration for the latter as opposed to outer-sphere structures for other complexes (Cl⁻, CO₄²⁻, etc.); and Magnusson¹⁰ has contemplated the possibility of charge transfer between F-and cation in contact. F- and OH- being isoelectronic and possessed of nearly identical radii and crystal fields, we write for both association processes

$$({\rm H_2O})_8 M^{3+} + L^- = ({\rm H_2O})_5 M L^{2+} + {\rm H_2O}$$

Because spectroscopic evidence indicates close equality of the crystal field stabilization of OH- and the replaced OH₂, and tabulated values of the crystal field splittings for OH₂, OH- and F- are usually very close, the symmetry change $O_h \rightarrow C_{iv}$ can be ignored.

Reaction (3) may then be envisaged as occurring in two stages: the removal of the sixth water ligand, then entry of L^- . Assuming a constancy of the M_{q}^{3} entropies, we can approximate the contribution of the first step to $\Delta G_{\rm ass}$ by equating it to minus one-sixth of the hydration enthalpy ΔH_h of each M^{3+} ion. The residual interaction of M^{3+} with L^- then consists of the crystal field stabilization by L^- which we equate (vide supra) to ΔU_{CF} for water, leaving the purely cation-anion integral-charge interaction ΔG_{ch} plus any covalent interaction ΔG_{CT} . Thus

$$\begin{split} \Delta G_{\rm ass} &= -\frac{1}{6}\Delta H_h - \frac{1}{6}|\Delta U_{CF}| + \Delta G_{\rm ass} + \text{constant} \\ \text{where } \Delta G_{\rm ass} &= \Delta G_{ch} + \Delta G_{CT} \\ &= \Delta G_{\rm ass} + \frac{1}{6} \left(\Delta H_h + |\Delta U_{CF}|\right) - \text{constant} \end{split}$$

Values of $\Delta G_{\rm ass}$ (Table 1) can then be interpreted in terms of variations in ΔG_{ch} or ΔG_{CT} or both. In Fig. 1, $\Delta G_{\rm ass}$ is plotted against $\Delta G_{\rm redox}$ for reaction (2). The oxidation potential E° for $OH_{\rm aq}^{\pm}=OH_{\rm aq}+\epsilon$ is given by Latimer^s, and for $F_{\rm aq}=F_{\rm aq}+\epsilon$ was calculated from the tabulation of Latimer by assuming, as for $OH_{\rm aq}$ (ref. 8),

† The dH_2 are conventional values for $M_g^{3+} + 3H_{sq}^+ = M_{sq}^{3+} + 3/2H_{2(g)}$; 1,000 added for numerical convenience.

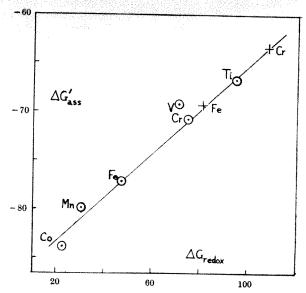

Fig. 1. Correlation between $\Delta G'^{ass}$, the standard free energy of association less water-displacement and crystal-field terms, and $\Delta G_{\rm red}$ for complete electron transfer (in kcal mole⁻¹). \bigcirc , Hydroxyl complexes; +, fluoride complexes.

that the solvation energy of fluorine atoms is small. No attempt has been made to correct $\Delta G_{\rm redox}$ for the juxtaposition neglected in reaction (2).

The approximate linearity in Fig. 1 (slope $\alpha = 0.22$), and especially the collinearity of the MF^{2+} with the MOH^{2+} data, favours a charge transfer contribution ΔG_{CT} as the important variable rather than the simple charge–charge interaction ΔG_{ch} . While current charge-transfer theory¹² does not encompass ΔG values, for structurally similar complexes these values are known often to follow the sequence of spectroscopic energies hv_{CT} which in turn, for M_{kq}^{2+} , bear a 1:1 relation to $-nFE^0$ values^{6,12}. The range of E^0 for Ti to Co represents 72 kcal mole⁻¹, and for the two anions, 33 kcal mole⁻¹.

We emphasize that Fig. 1 represents four essentially independent correlations, as shown in Table 2 where the slope α is calculated separately from each. In particular the last two,

$$\begin{cases} \Delta G_{\rm ass} \ ({\rm FeOH^{2+}}) \ - \ \Delta G_{\rm ass} \ ({\rm FeF^{2+}}) \end{cases} \div \\ \{ nFE^0 \ ({\rm F}) \ - \ nFE^0 \ ({\rm OH}) \} \ {\rm and} \\ \{ \Delta G_{\rm ass} \ ({\rm CrOH^{2+}}) \ - \ \Delta G_{\rm ass} \ ({\rm CrF^{2+}}) \} \div \\ \{ nFE^0 \ ({\rm F}) \ - \ nFE^0 \ ({\rm OH}) \}.$$

are independent of any assumptions about hydration of the cations, requiring only that ΔG_{ch} for F- and OH-, and likewise ΔU_{CF} , be approximately equal for interaction with any one cation. Differences between hydroxylation and fluoride complex formation thus seem entirely attributable to the different ionization energies of OH_{aq}^- and F_{aq}^- .

Table 2. SLOPE a FROM INDEPENDENT CORRELATIONS

Data for	Treatment	Dependence on	Slope a
MOH2+	Corrected for hydration		0.24
CrF ²⁺ and FeF ²⁺ CrOH ² and CrF ²⁺	Hydration "correction	$E^0(M^{2+})$	0.21°
FeOH2+ and FeF2+	cancels out	E'(OH-) and E'(F-)	0.22

This interpretation is not immediately applicable to Cl-, Br- or I- complexes because of differences (compare with L- above) in radii, crystal fields and repulsion

constants. Jorgensen's f and g parameters¹¹ might assist here in assessing the crystal field splittings.

Chemical Degradation of DNA oxidized by Permanganate

WHEN DNA is treated with potassium permanganate at 37° C and pH 9 for 19 h, the thymine, cytosine and guanine residues are oxidized, but the adenine residues are unaffected^{1,2}. The product (ODNA) is obtained in a high yield as a polymer in which there has been little degradation of the phosphodiester backbone of the DNA. Analytical data and the results of experiments on model compounds2-5 indicated that the thymine, cytosine and guanine residues had been oxidized to ureido residues. In view of the apparent lability of ureido sugars to alkali^{6,7} it seemed that the ODNA should be degraded by alkali to give oligonucleotides containing adenine. Previous work in which ODNA was degraded with alkali or with hydrazine followed by alkali seemed to support this, and from these results values for the distribution of adenine in DNA from a number of sources were obtained8,9. Reinvestigation of these reactions, and examination of other reactions of ODNA, however, have shown that the structure given before and the results quoted for the adenine distributions of the various samples of DNA were not correct.

Thus when ODNA was treated with the diphenylamineformic acid reagent introduced by Burton (2 per cent diphenylamine in 67 per cent formic acid at 30° C for 18 h)10, instead of the complete liberation of phosphorus as inorganic phosphate that was expected, there was only a 50 per cent liberation even after 3 days and then no further increase.

The reaction mixture which had been treated with the Burton reagent at 37° C for 4 days was fractionated on DEAE-cellulose and was shown to contain a number of non-ultraviolet absorbing organic phosphates. These were not obtained pure and were not completely They were, however, derivatives of characterized. 2-deexyribose glycosidically bound to a nitrogenous They did not give the typical yellow colour with Ehrlich's reagent, characteristic of urea derivatives, but they did give urea on strong acid hydrolysis.

These results indicate that ODNA contains both acid labile and acid stable groups. The former would include the adenine residues and probably urea residues; the nature of the latter is unknown.

The action of normal alkali on ODNA at 100° C for 1 h was studied in conditions similar to those used earlier2,8 but on a larger scale (800 mg of ODNA). The reaction mixture was fractionated on a column of DEAE-cellulose using a gradient of ammonium bicarbonate, as previously described2. Fifteen fractions were obtained, ten of which were identified as oligonucleotides containing adenine. Their position of elution from the column indicated that

there was present a series of oligonucleotides of increasing chain length of the general formula (nucleoside), (phos-Four of these ten fractions were further $phorus)_{n+1}$. fractionated by paper chromatography in propan-1-ol: ammonia (d, 0.88): water (11:2:7). (In this solvent the oligonucleotides had much higher mobilities than in the propan-2-ol: ammonia (d, 0.88): water (30:3:15) used previously and much better separations were obtained.) From each fraction several components containing adenine were obtained, but in each case one of the components was present in considerable excess. (In the range 60-67 per cent in the case of the di-, tri- and tetra-nucleotide fractions and 86 per cent in the case of the mononucleotide Measurement of the adenine to phosphorus fraction.) ratios of these components showed, however, that they were less than the theoretical values for components of the type A_nP_{n+1} (0.37, 0.53, 0.52, 0.65 compared with the theoretical values of 0.50, 0.67, 0.75, 0.80 for mono, di-, tri- and tetra-nucleotides, respectively).

The degradation of ODNA with hydrazine followed by treatment with benzaldehyde¹¹ and then alkali was similarly studied and in this case it was also apparent that the degradation was not specific, as shown by the hetero-

geneity of the oligonucleotide fractions.

These results show that ODNA is not specifically degraded to oligonucleotides containing adenine as previous results have implied. This discrepancy can be explained by the fact that the previous work was carried out on a smaller scale and with a different solvent system in which the heterogeneity of the fractions from the DEAE-cellulose column was not detected. The adenine to phosphorus ratios determined in the previous work were too high and this has been traced to a faulty sample of inorganic phosphate used to make standard phosphate solutions. The values given for the amounts of adenine in fractions of 2, 3, 4 and 5 units8,9 in the various samples of DNA are therefore too high.

The inorganic phosphate released by treatment of ODNA with normal alkali at 100° C for 1 h was 28 per cent compared with 54 per cent which would be expected if the degradation gave only oligonucleotides of the type A_nP_{n+1} (assuming a random distribution of nucleotides) and inorganic phosphate. In addition, a non-nucleotide organic phosphate identical with that detected in alkaline hydrolysates of apurinic acid and apyrimidinic acid (ref. 12 and unpublished results of Brammer, Jones, Mian and Walker) was also produced, but amounted to only 7 per cent of the total phosphorus. The fact that the total nonnucleotide phosphorus was only 35 per cent of the ODNA phosphorus also indicated that the alkaline degradation was incomplete.

Attempts have been made to obtain a complete and specific breakdown of ODNA. More drastic treatment with alkali could not be used because of the relative alkali lability of the adenine glycosidic linkage and of the adenine ring in 9-substituted adenines13. In order to try to avoid this, ODNA was treated with N-potassium sulphide (pH 12.5) at 100° C for 5 h. There was more degradation (52 per cent liberation of inorganic phosphate) than with normal alkali for 1 h, but 22 per cent of the adenine of the ODNA was liberated as free base and another 26 per cent was destroyed.

Deoxyinosine has been shown to be stable to alkali¹³, so that it was of interest to examine the action of alkali on deaminated ODNA. The deamination was carried out at pH 4·3 at room temperature for 17 h14. The deaminated product was treated with normal potassium hydroxide at 100° C for 7 h by which time the liberation of inorganic phosphate remained constant at 49 per cent. The products were fractionated on DEAE-cellulose and then by paper chromatography. Although no hypoxanthine and only a trace of deoxyinosine were detected, the oligonucleotides containing hypoxanthine obtained were found to be heterogeneous. This, and the fact that the release of inorganic phosphate was only 49 per cent, showed that in this case also a specific degradation was not

It therefore seems that ODNA contains both acid-stable and alkali-stable residues but it is not known whether the same residues are involved in each case. In this connexion it may be noted that when thymidine-5'-phosphate was oxidized with osmium tetroxide it was necessary to treat it with alkali before the phosphate was liberated as inorganic phosphate on treatment with the Burton reagent and that in the case of deoxycytidine-5'-phosphate there was incomplete liberation of inorganic phosphate even in these conditions15

BIOLOGY

Odour in Mice

LABORATORY mice sometimes produce a characteristic mousy smell, which on occasion can be obtrusive and unpleasant. This smell comes from the secretion of the preputial glands in the male, and its purpose is to mark territory or establish dominance. Certain conditions will provoke this secretion, among them putting the mice into a clean cage, which has to be promptly marked by the males. Thus, paradoxically, frequent cage changing will result in a smellier mouse room than one in which cages are changed only once in 2, 3 or 4 weeks. is perfectly compatible with health and hygiene if a suitably absorbent bedding material is used.

Recently, some surplus male mice had to be cutled from our colony, and they were put temporarily into an empty. clean polypropylene mouse cage before being taken to the killing chamber. After some minutes, there was a little fighting, but, much more noticeable, a very strong smell was produced. Our colony of some thousands of mice is normally almost free of smell, but these agitated male mice quickly made the room almost intolerable.

It is suggested that if a mouse colony is unpleasantly smelly, the remedy is not to increase the frequency of cage changing, but to examine the husbandry, and correct whatever faults are undoubtedly present.

Synergistic Effect of Two Stimulants to induce Probing in Stomoxys calcitrans (L.)

INVESTIGATIONS into the efficacy of mammalian skin secretions and their decomposition products, and of blood as stimulants of the probing response in blood sucking Diptera (other than mosquitoes) have produced confusing and often apparently contradictory results1-6. Hopkins4 used hungry, water-sated Stomoxys calcitrans in tests to determine possible chemical stimulants of probing, and obtained a positive response to conditions of high relative humidity and to ammonia evolved from aqueous solutions. This response to ammonia was observed in conditions of high humidity and did not occur when ammonia was evolved from dry ammonium carbonate. Hopkins, however, states that ammonia evolved from aqueous solution retains its stimulatory effect at low humidities. Measurements of relative humidity or of ammonia concentration were not made, although calculations of ammonia concentrations based on partial pressure data were given.

In the course of a detailed study of the physical and chemical factors which control feeding behaviour in Stomoxys calcitrans, I have obtained results which clarify the roles of ammonia and relative humidity in the initiation of probing. Hungry, water-sated flies were subjected to air, the temperature, relative humidity and content of any olfactory stimulant of which were precisely controlled. Dry air which had been filtered through charcoal was conditioned in a large reservoir; the required ammonia concentrations were achieved by injection and evaporation of calculated quantities of 0.880 ammonia solution. The humidity was then adjusted by injection of distilled water and the temperature was stabilized by drawing the air through glass coils which were immersed in a constant temperature water bath.

With this technique I found that ammonia did not induce probing at a series of concentrations from 50 µg/l.-2 mg/l. at 65-70 per cent relative humidity. These concentrations of ammonia also failed to elicit probing at relative humidities ranging from 25-85 per cent when the flies were conditioned to the relative humidity in question. Flies which were, however, conditioned to any level of humidity within this range, and which were then subjected to a sudden increase in relative humidity, probed in the absence of any olfactory stimulant. Adaptation to the new level of humidity was extremely rapid and the response usually disappeared completely within 30 sec.

I carried out an experiment in a constant temperature room at 25° C and 50 per cent relative humidity to determine the effect of the presence of ammonia on this response to an increase in relative humidity. Groups of forty flies which had been starved for 24 h and deprived of water for 1-3 h were subjected individually to increases in relative humidity from the ambient 50 per cent, to 65, 75, 85, 95 and 100 per cent relative humidity, both in clean air and in air containing 1.4 mg/l. of ammonia (shown in preliminary experiments to be the optimal concentration). The flies were observed for 1 min after the rise in humidity and the results are shown in Fig. 1. There is clearly a synergistic effect between the two stimuli in the induction of probing. The nature of the synergy is unknown. Association between ammonia and adsorbed water molecules may result in the stimulation of a single receptor site. Alternatively, two types of receptor may be involved, and the synergy could be a central nervous system phenomenon. Further work is required to resolve this problem.

An insect approaching the skin of a live host would be subjected to an increase in humidity and to a series of olfactory stimuli, including ammonia. The concentrations of ammonia shown to be effective in these experiments are very much higher, however, than could be expected to result from the decomposition of skin secretions on the host's surface. It is thus possible that in the presence of

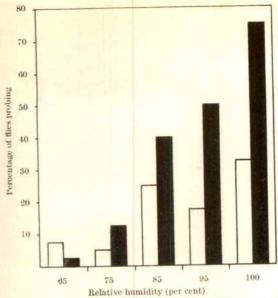

Fig. 1. Percentage probing responses of Stomoxys calcitrans. Flies were conditioned to 50 per cent relative humidity and probing was observed in response to rapid increases in relative humidity to five levels, in the presence (■) and in the absence (□) of 1·4 mg/l. ammonia.

other chemical and physical stimuli on the host's body surface, ammonia influences the probing response at much lower concentrations.

I thank Dr C. T. Lewis for his help and criticism. This work was financed by a grant from the Ministry of Overseas Development.

Identification of the Pokeweed Mitogen in Africa

In 1960, Nowell¹ first described a plant lectin from Phaseolus vulgaris—phytohaemagglutinin, which sessed mitogenic activity for human peripheral blood lymphocytes, that is, the ability to transform the resting lymphocyte into blast like cells. Subsequently, a second phytomitogen was reported in saline extracts of the plant Phytolacca americana—the pokeweed mitogen. In recent studies in our laboratory^{3,4}, we identified and isolated pokewood mitogen in an electrophoretically homogeneous form by preparative multiphase zone electrophoresis on polyacrylamide gel columns and we have shown that it possesses haemagglutinating, leukagglutinating and mito-Further chemical characterization⁵ regenic activity. vealed that pokeweed mitogen is a glycoprotein with a molecular weight of 32,000 containing 3.2 per cent monosaccharide, 1.4 per cent hexosamine and unique aminoacid composition with thirty-three cystine residues. In addition, biochemical, physiochemical and immunochemical studies revealed that pokeweed mitogen differed from p'aytohaemagglutinin in a number of important ways4,5.

The plant species Phytolacca americana—pokeweed a perennial, seems to be homogeneous in the United States and Europe*. In a recent botanical survey of the genus Phytolacca, we have isolated and identified the pokeweed mitogen from plants from various parts of the United States and have demonstrated that it is present in all parts of the plant with the highest concentration in the root. Of special interest immunologically is the effect of pokeweed mitogen on the circulating lymphocyte. Transformation of resting lymphocytes by pokeweed mitogen in vitro produces a spectrum of blast-like cells, predominant among which are cells bearing fine structural resemblance to the phytohaemagglutiniu transformed cell and a distinctive cell type with the cytoarchitectural features of the plasmablast or immunoblast7. In addition, Barker et al. 8 have recently called attention to the specific haematological effects of pokeweed mitogen in a study of twenty-six children who sustained systemic exposure to pokeberries. These children developed a blood picture characterized by an absolute plasmacytosis, eosinophilia and platelet phagocytosis without other evidence of systemic disease.

In the light of the specific role and interrelationship of lymphocytes, plasma cells and precursor blasts in immunological, lymphoproliferative and neoplastic states, the observation that pokeweed mitogen induces distinctive morphological changes of immuno-competent cells both in vivo and in vitro may be of considerable biological importance. Recently, in a comparative electron microscopic analysis of the AL-1 and EB-2 Burkitt lymphoma cell lines, Douglas, Borjeson and Chessin's have reported that in both established cell lines, there is a spectrum of blast-like cells ranging in type from those which display a well developed Golgi apparatus, non-aggregated ribosomes and sparse endoplasmic reticulum to cells containing numerous aggregated ribosomes and an extensively developed rough surface endoplasmic reticulum with dilated cisternae. Furthermore, in both Burkitt cell lines, cell types are present which bear resemblance to the phytomitogen (phytohaemagglutinin, pokeweed mitogen) transformed blast cells. It was therefore of considerable interest to us to investigate the presence of mitogenic activity (pokeweed mitogen) in Phytolacca dodecandra (African pokeweed) especially in the areas in Africa where the

Burkitt lymphoma is found.

One of us identified and gathered material of Phytolacca decandra L. (Fig. 1) in the vicinity of Ibadan. Nigeria. Individual specimens of the berry, stem and roots were finely ground, extracted with isotonic saline, lyophilized and isolated by the previously described methods of Borjeson et al.3. The material was analysed by multiphase zone electrophoresis in 13 per cent and 7.5 per cent polyacrylamide gels without urea according to the procedure described by Reisfeld et al.5. For the isolation and characterization of specific bands, duplicate gels of the American and African pokeweed mitogen varieties, electrophoresed in parallel, were fixed with trichloroacetic acid. The R_F value of each band was determined from the relative position of the buffer front marked with brom-phenol blue to that of the protein bands precipitated with TCA. Having determined the RF value of each band, duplicate gels not fixed with TCA were then out into 1 mm sections and the material from each section eluted in 0.01 molar phosphate buffered saline pH 7.4 and assayed for haemagglutinin and mitogen activity by the methods previously described3. The principal biologically active mitogen band with an RF (0.43) value similar to the American pokeweed mitogen was identified on analytical disc electrophoresis (Fig. 2). Additional bands not present in Phytolacca americana were also seen. Further isolation and characterization of this material revealed that this substance is a glycoprotein and has an ultraviolet absorption spectrum with a maximum at 280 mμ and a secondary peak at 290 mμ similar to the American variety. Haemagglutinating and mitogenic assays performed on the African pokeweed mitogen

isolated at an R_F 0.43 revealed that it possessed similar biological activity to the American variety. Immunodiffusion studies in agar gel revealed that the African pokeweed mitogen (saline extract) displayed numerous antigenic determinants in common with the American

variety using a rabbit antiserum prepared against

American pokeweed mitogen¹ (Fig. 3).

The finding that the Phytolacca dodecandra (African pokeweed) and Phytolacca americana (American pokeweed) possess chemically similar mitogens (pokeweed mitogen) indicates that this plant glycoprotein is common to the genus. Furthermore, the demonstration of a biologically active mitogen in African pokeweed may be of considerable haematological and immunological importance in view of the fact that extracts and preparations of pokeweed have wide medicinal and nutritional applications in Africa10.

We thank Mr D. P. Stanfield, Agricultural Director of Forest Research for western Nigeria, for his assistance with the collection of the African pokeweed.

Shell Disease of Ostrea edulis L.

SHELL disease on native oysters in Britain initially became established in Essex¹. It is now well established there and is present in natives in beds at Whitstable and in Cornwall. It has also been found in Clew Bay, Eire (unpublished report by C. Duggan to Irish Fisheries Department). Authors have suggested that oyster shell disease is caused by the presence of a fungus in the shell². No clear descrip-

tion of the organism can be traced.

The pathology of the disease has been frequently described 1.2 and essentially two stages can be recognized. Initially, the disease appears as tiny chalky white specks on the inner surface of the shells. In contrast to the naturally occurring chalky patches, the disease spots have a definite relief, giving the shell in these areas a rough texture. These spots coalesce, and may eventually cover one or both valves. The advanced stage of the disease is recognized as the development of green or brown rubber like spots or warts of conchyolin. Frequently these warts are associated with the attachment of the adductor muscle.

In all oysters examined in this investigation, a fungus has been found present in diseased areas. In preparations of shell in diseased regions the fungus is apparent as a dense network of mycelium. These are of a slight brown tint and quite distinct from the shell boring algae which are present in most shells. The mycelium is 2μ wide, with small ovoid dilations occurring at irregular intervals

(chlamydospores) and measuring $4 \times 6\mu$.

Further detail is only revealed by removing the opaque matrix of shell. The most satisfactory method of decalcification has been found to be the use of the chelate disodium diaminoethylenetetraacetate (EDTA(Na₂))³ which does little structural damage to the shell infesting organisms in question. Diseased shell material decalcified in a 5 per cent solution of sodium EDTA in distilled water leaves only the horny conchyolin warts and a gelatinous substance which is the protein matrix of the shell. Squash preparations of the latter show the presence of fungal hyphae which are hyaline and may be irregularly septate.

It has been suggested^{1,2} that this disease is the same as that known to the French as "maladie du pied". Specimens received from France indicate that shell disease and "maladie du pied" (a variant of which is "Maladie de la charnière") are the same both in the gross nature of pathological effects produced and in the vegetative

structures of the fungus present.

Recently a fungus has been repeatedly isolated from diseased oysters. When grown in liquid media poor in nutrients, the fungus normally remains mycelial, being hyaline, septate in older portions with the characteristic chlamydospores (Fig. 1). These chlamydospores may

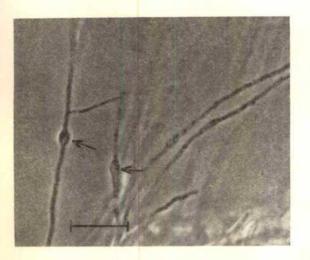

Fig. 1. Fungus from liquid yeast extract peptone medium showing chiamydospores. Phase contrast. Scale equals 10μ .

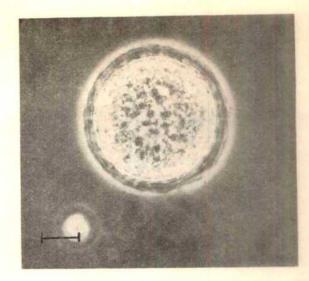

Fig. 2. Mature sporangium showing two-layered wall, the outer layer being thick, gelatinous and laminate. Phase contrast, Scale equals 20μ .

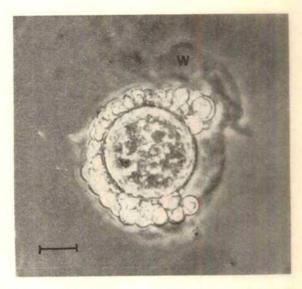

Fig. 3. Zoospore release from sporangium. Ruptured gelatinous layer visible (W). Phase contrast. Scale equals 20μ .

germinate to give rise to spherical sporangia, 30–120µ in diameter, which separate readily from the mycelium, do not have rhizoids and are then free floating. When mature, the sporangial wall is seen to be composed of two layers, the outer layer being gelatinous (Fig. 2). Biflagellate zoospores are formed within the sporangia (Fig. 3) and are diplanetic. The secondary cysts germinate to give rise to sporangia. Once the sporangial state occurs in liquid media (yeast extract peptone) it is then maintained without reversion to the mycelial condition. No sexual stages of this fungus have been seen in the material examined.

This description suggests that this organism should be classified as Phycomycetes, Biflagellatae, Saprolegniales. The eucarpic thallus rules out the families Ectrogellaceae and Haliphthoraceae while the presence of a well developed mycelium and the lack of a rhizoidal system rule out the Thraustochytriaceae. The fungus shares the extensive mycelium characteristic of the Saprolegniaceae, but the zoospores are markedly smaller in size and no sexual stage has been observed.

This seems to be the first time that the fungus which is always found in diseased oysters has been cultured. The epidemic nature of this disease could well be explained by the prolific production of zoospores obtained under suitable conditions.

Yield Increase from Sorghum Hybrids

In variety trials at thirty sites or seasons in East Africa, the grain yield of the hybrid $H \times 58$ when plotted against the yield of 'Serena', its pollinator parent, showed a linear regression with a coefficient value which did not differ from $b=1\cdot 0$ (ref. 1). This same effect has been obtained from other areas, as shown in Table 1.

The first four entries in the table give comparisons of a good variety with a good hybrid. In each case there is a significant linear regression with a coefficient value which does not differ from b = 1.0. Figure 1 illustrates the results from the United States, and is typical of the graphs obtained from the first three entries of Table 1. Yields obtained from the first three entries of Table 1. of 'Martin' varied widely, from 250 kg/hectare to 7,400 kg/hectare, but in the whole of that range the hybrid gave a constant yield increment: there was no interaction of genotype with environment; the increase from the hybrid was independent of the standard of farming. It would be meaningless to express the increase in yield from the hybrid as a percentage, unless the yield level of the variety were specified. None of the entries in Table 1 gives any support for the idea of slightly increased plant efficiency as a result of heterosis, giving greater expression with good farming than with poor farming.

In the case of the fifth entry in Table 1, the regression indicates a greater benefit from growing the hybrid at high yield levels than at low levels, but the variety 'SB 65' is susceptible to anthracnose, while $H \times 57$ is resistant. In the lush conditions which give high yield the disease is more prevalent and the yield of the 'SB 65' is relatively more depressed. In India the situation seems to be reversed, for the yield advantage of the hybrid becomes less at high varietal yield levels. This can be attributed to differential susceptibility to pests. The hybrid CSH-1 is susceptible to central shoot fly (Atherigona varia) and to the stem borer Chilo4. The local check varieties are resistant, and in the data there are a number of sites where the variety yielded substantially more than the hybrid. This comparison is in any case not as reliable as the others, because the variety is the "local" of the yield tables, differing from place to place. There seems to be no reason to doubt that for hybrids and varieties

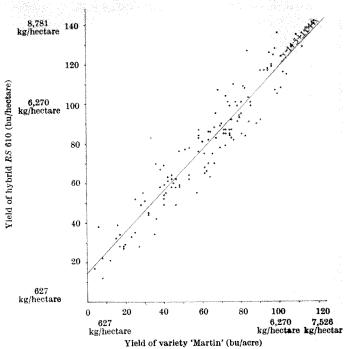

Fig. 1. Regression of yield of hybrid RS 610 on yield of variety 'Martin' in the United States.

with similar levels of resistance to the local pests and diseases, the pattern found in the United States, East Africa and Rhodesia, will also apply to India.

There are obvious practical implications for the relief of hunger: as soon as a hybrid with a yield advantage of 1,000 kg/hectare is available, and it soon will be, and is being grown on 10 million of India's 18 million hectares under sorghum⁵, there will be an additional 10 million tons of grain produced, as long as the fertility is available to produce that amount of grain.

The pattern in the United States supports this view. The mean yield of sorghum for the 3 yr before hybrids were introduced (1954-56) was 1,280 kg/hectare, over 4.6 million hectares. The mean yield for the 3 yr 1962-64 was 2,750 kg/hectare over 4.9 million hectares. About 1,000 kg/hectare of this increase can be ascribed to the hybrids: the remaining 400 kg/hectare or so have probably come from better farming, which would have given the same increase on varieties as on hybrids. Evidently, there must be a lower limit of farming below which the results deduced from the figure cannot apply: all the trials examined have had reasonable treatment; fertility has not been limiting.

The main expression of heterosis for yield in sorghum is in increased grain number, which may be almost doubled relative to the better parent. The small increases in height, stem thickness, leaf area, forage and tiller number could together add up to quite a large increase in photosynthetic area. It seems that in the trials studied, the hybrid floral buds must have produced more florets per hectare than the variety, with a constant increase for a wide range of conditions. The plant factory could

Enzyme Detoxication of 3',4'-Dichloropropionanilide in Rice and Barnyard Grass, a Factor in Herbicide Selectivity

THE herbicide, 3',4'-diehloropropionanilide (DCPA, also known as 'Propanil', 'STAM-F34' and 'DPA'), inhibits photosynthesis and has the remarkable property of selectively destroying barnyard grass (Echinocloa crusgalli) in fields of rice (Oryza sativa L.)2.

DCPA is converted to DCA by soil micro-organisms³ and acylanilide hydrolases of mammalian liver4 and a pseudomonads. We have inferred from these studies, and others less well documented, that similar enzyme destruction might occur in higher plants and that the observed selective toxicity might be attributed to differential rates of destruction in rice and barnyard grass.

We have confirmed our expectations with the discovery that cell free extracts of rice contain a heat labile macromolecule able to catalyse the transformation of DCPA to DCA and other products. Extracts prepared in the same way from barnyard grass were usually devoid of activity or at most had one-twentieth of the activity of rice.

Rice varieties 'Belle Patna', 'Bluebonnet' and 'IR-8' were obtained from the US Department of Agriculture. Barnyard grass seeds, from the same source, were purified to less than 1 per cent contamination by other seeds. All samples of DCPA were given by the Rohm and Haas Company. Seeds were germinated in tap water at 30° C with frequent changes of water for 60 h. Seedlings, grown in 'Vermiculite' in the greenhouse, were collected at the three leaf stage. All aerial parts of these seedlings were collected.

Seeds, germinating seeds and seedlings were frozen in liquid nitrogen and reduced to a fine powder in a Waring The powder was then partially thawed and extracted with 50 mmolar tricine (N-tris-hydroxymethyl methylglycine) buffer at pH 8.5. The extracts were adjusted as required to pH 8.5 with sodium hydroxide, and squeezed through cheesecloth to remove solid debris. Remaining debris and heavy particles were removed by a brief centrifugation at about 500g. Extracts of barnyard grass were concentrated with 'Carbowax 7500' (polyethylene glycol, Union Carbide) in order to obtain detectable levels of activity.

Enzyme assay was performed essentially as described by Kearney⁵ and DCA was determined colorimetrically as described by Pease⁶. Assay mixtures contained 2.5 ml. of buffered extract and 1 µmole of DCPA dissolved in 1 μl. of absolute ethanol. Incubation was at 30° C with slight agitation on a waterbath shaker. For colorimetric

* Dry seeds and germinating seeds gave nearly identical values.

† Estimated value obtained from concentrated extract.

readings, samples were partitioned with chloroform and separated by centrifugation. The unit of activity is defined as the amount of enzyme activity producing 6.2 mumoles/h in the conditions described.

A comparison of the activities of extracts of rice and barnyard grass appears in Table 1. We estimate that dry rice seed is able to produce at least 2.5 µg of DCA/h/g of fresh weight and that the three leaf seedling is sufficiently active to produce 10 to 25 µg/h/g of fresh weight.

Our rice preparations contained no intact chloroplasts. but membrane fractions rich in chlorophyll, loosely termed "grana", were prepared by differential centrifugation and proved to be very active. The data presented in Table 2 show most of the activity sediments with the grana. Attempts to solubilize the enzyme with butanol resulted in total inactivation, and sonication at 20,000 c/s for 30 min was without effect. DCA formation by the particulate enzyme was linear with time (Fig. 1).

Table 2. Separation of 3',4'-dopa hydrolase activity from bice by differential centrifugation

Supernatant	Colour	v/ml.	Per cent of initia
1,000g, 5 min	Dark green	4.9	100
2,500g, 5 min	Dark green	5-2	100
10,000g, 15 min	Light green	1.5	30
$10,000g, 60 \min$	Light green	1.6	30*

* The remaining 30 per cent could be reduced to 10 per cent by dialysis followed by centrifugation. This step also sedimented the remaining chlorophyll. The activity removed from the extract was accounted for by the activity recovered from the sedimented fractions.

The products of the reaction were determined by thinlayer chromatography after 2 h incubation of a dialysed. soluble portion of the rice enzyme with ring-labelled ¹⁴C-DCPA. An ether extract of the reaction mixture was transferred to methanol, applied to a silica gel thin-layer plate, and developed in chloroform: methanol: pyridine (100:5:1). The results (Fig. 2) show that DCPA was transformed into six products, numbered on the figure in order of decreasing radioactivity. Quantitation of the radioactivity showed that 23 per cent of the substrate was transformed. DCA accounted for about 13 per cent of the transformed radioactivity and nearly all of the rest remained at the origin.

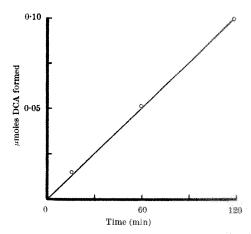

Fig. 1. Formation of 3,4-dichloroaniline in rice extracts. The enzyme was obtained from the particulate fraction. Each point represents the amount of DCA formed from 1 μ mole of DCPA added at zero time.

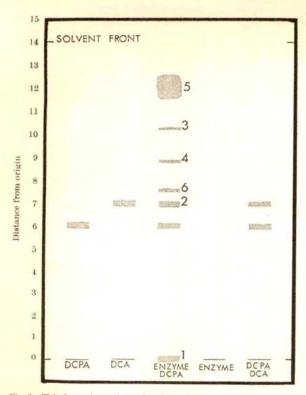

Fig. 2. Thin-layer chromatography of transformation products of DCPA formed in rice extracts. The enzyme was obtained from the scluble fraction, concentrated four-fold by carbowax and dialysed against 5 mmolar buffer at pH 8-5. Spots were located under ultraviolet illumistion and quantitated by liquid scintillometry. The enzyme reaction mixture contained 40 μ moles of DCPA at a specific activity of 0-25 μ c./ μ mole. Products 3-6 represent about 0-4 per cent of the total radioactivity.

These results suggest that acylanilide hydrolase is one of several enzymes acting on DCPA or at the end of a catenated set of enzymes; therefore we cannot equate detoxication of the herbicide simply with the formation of DCA. But it is equally clear that acylanilide hydrolase activity is strongly correlated with the resistance of the rice plants to herbicide action.

Detailed investigation of this enzyme will be important not only because of the importance of rice in world food production but also for an elucidation of biochemical mechanisms in a form of selective toxicity.

We thank Dr C. Roy Adair, of the US Department of Agriculture, for seeds used in this investigation, and Drs Roy Yih and D. H. McRae, of the Rohm and Haas Co. Research Laboratories at Spring House, Pennsylvania, for samples of 'STAM-F34' and communication of their research data. Effect of Gibberellic Acid on Genetically Controlled Tumour Formation and Vascularization in Tomato

SEVERAL effects of gibberellic acid on plant growth and differentiation have been recognized 1-4, but there have been no previous reports of any effect on tumorous genotypes in vivo. This communication reports the effect of gibberellic acid on a genetically controlled condition resembling a tumour and on vascular development in a tomato hybrid. The tumour condition appears on the hybrid plants carrying the Frosty spot (Frs) gene from Lycopersicon chilense on the background of L. esculentum variety 'Tiny Tim', and is transmitted as a dominant trait5. Tumours consisting of groups of undifferentiated parenchymatous cells develop along the veins of the leaves, after which the affected tissues become chlorotic and necrotic5,6. Plants with a tumour trait appear dwarfed and have poorly developed vascular tissue, which results in weak stems. The non-tumorous plants, however, are normal and show good vascular development. In the tumorous plants, differentiation of vascular tissue stops after three to six layers of secondary xylem have been formed (Fig. 1A). In contrast to this, the derivatives of cambium in the normal genotype are many and show relatively more lignification in the secondary xylem (Fig. 1B).

We tested for several plant hormones (kinetin, auxin and gibberellic acid), but only the specific effects of

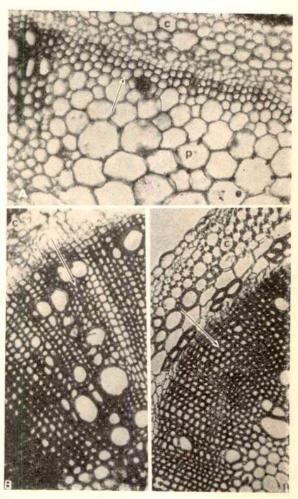

Fig. 1. Transverse sections of tomato stems, $\times 125$. A, Stem from a tumorous plant; B, stem from a non-tumorous plant; C, stem from a tumorous plant sprayed with gibberellic acid. Secondary xylem is indicated by arrows, pith by the letter p and the cortex by c.

gibberellic acid will be described here. Young plants (2-3 months old) of tumour and non-tumour tomato genotypes were sprayed with gibberellic acid dissolved in distilled water. No wetting agents were used in these experiments. Control plants were sprayed with distilled water. One dose of 2 mg of gibberellic acid in 2 ml. of water was sprayed all over the plant, effectively inducing secondary xylem differentiation, and doses of 10 mg in 10 ml. of water sprayed over a period of 5 days did not recognizably harm the plants. Plants were kept in the greenhouse which was maintained at about 23° C. For anatomical studies, transverse sections were cut with a hand razor at different distances along the stem, stained with safranin and mounted in 50 per cent glycerine.

The tumorous plants which had been sprayed with gibberellic acid elongated rapidly, and during the elongation period the new leaves which emerged after the treatment did not develop tumours. When further elongation ceased, these plants developed tumours on the leaves and continued to do so until they died. The stems of the treated tumour plants were stiffer and sturdier than the untreated tumour plants. The observed effects of gibberellic acid on the non-tumour tomato plants included rapid elongation of the stem (Sachs7 and Paleg8) and earlier stiffening of treated stem compared with untreated non-tumour plants.

Table 1. EFFECT OF GIBBERELLIC ACID ON THE DEVELOPMENT OF SECOND-ARY VASCULAR TISSUE

Genotype and treatment	Diameter of stem in mm serial sections	No. of layers of secondary $xylem \pm S.E.$
Tomour untreated	2·0 2·5 4·0 6·0	$\begin{array}{c} 0 \\ 3\cdot1 & \pm 0\cdot27 \\ 3\cdot8 & \pm 0\cdot19 \\ 6\cdot7 & \pm 0\cdot87 \end{array}$
Tumour sprayed with gibberellic 2 mg (21 days)	acid 2:0 1:8 2:5 3:0	$\begin{array}{c} 6 \cdot 25 \pm 1 \cdot 04 \\ 9 \cdot 6 \ \pm 0 \cdot 27 \\ 16 \cdot 5 \ \pm 0 \cdot 56 \\ 16 \cdot 4 \ \pm 0 \cdot 74 \end{array}$
Non-tumour control	2·0 2·5 3·0 4·0 4·5	$\begin{array}{c} 0\\ 8\cdot 9 & \pm 0\cdot 30\\ 7\cdot 25 \pm 0\cdot 30\\ 15\cdot 7 & \pm 0\cdot 76\\ 26\cdot 2 & \pm 1\cdot 97 \end{array}$

The anatomical analysis of the treated and control tumour and non-tumour plants is presented in Table 1. It is clear that development of secondary xylem proceeds at different rates in the untreated tumour and non-tumour stems. For example, in stems about 4 mm thick, the average number of secondary xylem layers is 3.8 in the tumour genotype (and consists mostly of tracheids or narrow diameter xylem elements), while in the non-tumour stem the number of secondary xylem layers averages 15.7 (and consists of numerous enlarged xylem vessels). The tumour stem was sectioned 21 days after treatment with 2 mg of gibberellic acid, and showed greater vascularization and lignification of vessels than did the untreated stem (Fig. 1C). More than 2 weeks are required before the effects of gibberellic acid are noticeable on vascularization.

The evidence presented here indicates that plants carrying the Frs gene are unable to form an adequate vascular system for self support, and show a growth which resembles a tumour on the leaves. This implies an association between tumorigenesis and vascularization. It was suggested recently that a tumorous condition on tomato leaves probably results from an abnormal auxin metabolism. These abnormalities, associated with the presence of the Frs gene, can be partly overcome by an exogenous supply of gibberellic acid. It seems reasonable to suggest that the Frs gene interferes with, among other things, the metabolism of substances which are similar to gibberellin and which are essential to normal plant growth. There is considerable evidence that auxin (indolyl-3-acetic acid) plays an important part in differentiation of vascular tissue in plants⁹⁻¹¹. Whether exogenous gibberellic acid is involved in the mobilization of the auxin from the leaves to the stem for vascularization, or induces the synthesis of endogenous auxin in the stem, or whether it is directly involved in the induction of secondary xylem differentia-

tion and recovery to normal state, remains to be investigated.

We thank Dr Ian Sussex and Dr G. L. Hagen for helpful comments and Lawrence E. Cranch for technical assistance. The work was supported by grants from the US Public Health Service and by a grant from the Cairnerest Foundation.

Antagonism of Tryptamine Stimulated Growth in Apices of Avena Coleoptile by Xylamidine Tosylate

XYLAMIDINE tosylate has been shown to antagonize peripheral actions of 5-hydroxytryptamine in isolated rat uterus and in a variety of in vivo tests with rats1. In studies of the role of tryptamine and other indole compounds in promoting the growth of excised Avena coleoptile apices I have found that xylamidine tosylate is a powerful antagonist of tryptamine stimulated growth in this plant tissue.

The procedure for growing Avena coleoptiles and the methods of experimentation were described earliers Excised apical sections were 10 mm long. Concentrations of xylamidine tosylate of 10-4 molar, and more, markedly inhibit the extension growth of the coleoptile sections. After a 22 h growth period at 25° C coleoptile sections treated with 10^{-4} molar xylamidine to sylate grew 1.7 mm compared with 5.1 mm of growth in the controls. Concentrations of xylamidine tosylate of 10-5 molar and less do not affect linear growth. Apical sections of Avena coleoptiles respond to exogenous indolyl-3-acetic acid (IAA); at 10-3 and 10-6 molar the response is an increase in linear growth. Treatment with xylamidine tosylate at concentrations of 10-5 molar and less does not alter this response in any way (Table 1). The inhibition of growth by xylamidine tosylate at 10⁻⁴ molar is partially relieved by IAA.

The growth of Avena coleoptile apices is also promoted by tryptamines, which, when incubated with Avena colcoptile sections in the presence of xylamidine tosylate, does not promote growth (Table 2).

10 ⁻⁶	$3 \cdot 1 \pm 0 \cdot 2$	6·7 ± 0·4	6.9 ± 0.3	6.4 ± 0.4	6·6±0·4
0	$1 \cdot 7 \pm 0 \cdot 1$	5·0 ± 0·4	4.7 ± 0.2	4.7 ± 0.4	4·8±0·3

The increase in growth increment after 22 h of growth at 25° C is expressed in fmm $\,\pm\,$ the standard error of the mean of ten replicates.

Table 2. EFFECT OF XYLAMIDINE TOSYLATE ON TRYPTAMINE STIMULATED GROWTH IN Avena COLEOPTILE APICES

(moles/l,) 10 ⁻¹	10-5 10-6	10-4	
10-6 1.9 ± 0.2 4.9	2 ± 0.4 5.2 ± 0.5 9 ± 0.4 5.4 ± 0.3 0 ± 0.4 5.1 ± 0.4	5.0±04	9-3 ± 0-8 7-1 ± 0-6 76-8 ± 0-4

Growth increment was measured as in Table 1.

Xylamidine tosylate antagonizes the action of tryptamine in plant tissue in a manner analogous to its antagonism of the action of 5-hydroxytryptamine in animal tissues1. Furthermore, the concentrations of xylamidine tosylate which are effective in antagonizing the effect of the indole amines in both plant and animal tissue are smaller than toxic concentrations. In plant tissues, enzymes able to convert tryptamine to IAA have been extensively studied2-4,7, and it is well established that tryptamine is converted to IAA by plant tissues. Inhibitors of amine oxidases have been shown to prevent the formation of IAA from tryptamine^{5,6}, and to inhibit growth stimulated by tryptamine in excised Avena coleoptile apices. The effect of xylamidine tosylate in the experiments with Avena coleoptiles reported here is similar to that of amine oxidase inhibitors; in view of this it is tempting to suggest that, in the coleoptile tissue at least, xylamidine tosylate acts in an analogous if not an identical manner to the amine oxidase inhibitors, by blocking the conversion of tryptamine to IAA. This conclusion is supported by the data of Table 1, where xylamidine tosylate does not affect IAA induced growth.

Whether xylamidine tosylate antagonizes the action of 5-hydroxytryptamine by a similar mechanism is not known. It must be remembered that indoleacetaldehyde is an intermediate in the conversion of tryptamine to IAA² and that xylamidine tosylate could exert its effect either before or after the formation of the aldehyde.

I thank Dr H. F. Hodson for xylamidine tosylate and Angela Barker for technical assistance.

IMMUNOLOGY

Cell Viability in Leucocyte Cultures stimulated with Phytohaemagglutinin

While investigating the effect of various tissue extracts on the division of cells stimulated with phytohaemagglutinin (PHA) we noticed that in control cultures with PHA there seemed to be a significant increase in the number of non-viable cells. We recorded the number of viable cells and the total number of cells in thirty-eight subsequent experiments. The viability of cells grown with PHA is important in view of previous observations on the cytotoxic action of lymphocytes after exposure to PHA1,2, and the use of PHA in patients with aplastic anaemias3,4. The changes also affect the quantitation of cell responses in culture.

Defibrinated or heparinized venous blood from healthy blood donors was used and leucocyte cultures were prepared from leucocyte rich plasma. The method of culture was essentially that of Moorhead, Nowell, Mellman, Battips and Hungerford⁵ except that 0.3 ml. of PHA was only added to one of a paired culture. Phytohaemag-glutinin was obtained from Burroughs Wellcome and three different batches were used. The amount of nutrient (TC 199) and autologous plasma was the same in both cultures. Lymphocytes were obtained from defibrinated blood by the technique of Coulson and Chalmers using carbonyl iron particles and methyl cellulose. Lymphocytes were also obtained by the method of Rabinowitz7, by passing plasma rich in leucocytes through a column of glass beads; both methods gave 90 per cent or more lymphocytes.

The lymphocytes were cultured in a manner similar to the leucocytes. Cultures were examined at intervals of 3 and 6 days. On each occasion the number of white cells, cell viability, blastic transformation and uptake of tritiated thymidine were assessed in each of the paired Viable cells were assessed as the cells which cultures. excluded dye after exposure to 1 per cent trypan blue for 30 min at 37° C. The number of transformed cells in each culture was recorded while examining 500 cells, and expressed in absolute numbers per cm³ of culture. cells incorporating DNA before division were estimated These were prepared from each by autoradiography. culture; samples of 1 ml. were exposed to 5 µc. of tritiated thymidine (specific activity 4.2 c./mmole) for 1 h. The cells were fixed and spread on glass slides, coated with nuclear gel emulsion (Ilford G 5), exposed in the dark at 4° C for 6 days and then developed. The cells beneath the emulsion were stained and the number of labelled cells was recorded in each cm3 of culture.

In the control cultures of leucocytes or lymphocytes grown alone the degree of blastic transformation was never more than 2 per cent and the uptake of tritiated thymidine was less than 0.5 per cent.

In five out of sixteen 3 day leucocyte cultures there were more white cells when the cultures were stimulated with PHA. The number of non-viable cells was markedly increased in the cultures stimulated with PHA (P < 0.01); in most cultures there were twice as many dead cells as in the corresponding control cultures. The absolute number of transformed cells was correlated with the number of viable cells in the cultures, as was the number taking up tritiated thymidine. There was a considerable scatter of results (Fig. 1) and they are not statistically significant. For blastic transformations $r_{xy} = 0.37$, P > 0.1, n = 12; for uptake of tritiated thymidine $r_{xy} = 0.19, P > 0.1, n = 14.$

In five out of twenty-two 3 day lymphocyte cultures the white cells were increased in the cultures containing PHA, and the number of viable cells was increased in four of these cultures. The number of non-viable cells was significantly increased in the cultures stimulated with PHA, P < 0.001. There was good correlation between the number of viable cells in the stimulated cultures and the degree of blastic transformation (Fig. 1) and uptake of tritiated thymidine, and the results are highly significant. For blastic transformation $r_{xy} = 0.96$, n = 21; for tritiated thymidine $r_{xy} = 0.91$, n = 17; and in both cases P < 0.001.

In half the 6 day leucocyte cultures there were more cells in the cultures treated with PHA than in the controls.

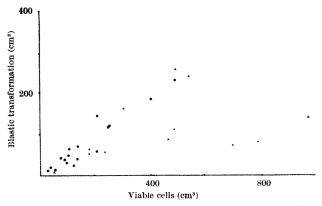

Fig. 1. Relationship of viable cell count to blastic transformation in cultures 3 days after stimulation with PHA. A. Leucocytes; •, lymphocytes.

In seven out of eighteen lymphocyte cultures the number of viable cells was greater in the treated culture. The number of non-viable cells was still significantly more in the PHA cultures. The degree of correlation of uptake of tritiated thymidine with the viable cell count is not as good in the 3 day cultures, but is still statistically significant. For 3 day cultures $r_{xy} = 0.91$, P < 0.001, n = 17; for 6 day cultures $r_{xy} = 0.88$, P < 0.001, n = 15.

The difficulties of evaluating changes occurring in cell cultures especially in the presence of PHA are well known. Nevertheless, with care in sampling the findings reflect the happenings in the culture. The results we obtained repeatedly and significantly indicate that the PHA used in our cultures had a marked cytotoxic effect on the growing cells. This effect was observed in both leucocyte and lymphocyte cultures, and the numbers of non-viable cells were greater in the leucocyte cultures. The non-viable cells were of varying sizes although large round cells seemed to be the most prominent cell in our 3 day cultures; very few granular cells remained.

We do not know yet whether PHA is equally toxic to cells from all parts of the body or whether this effect occurs only in vitro. Sarkanys has demonstrated a toxic effect on human embryo liver cells in vitro, and we have observed increased cell death in splenic cell cultures. The cytotoxic effect of lymphocytes found after exposure to PHA² may be a product of lymphocyte death rather than an immune reaction. How these findings relate to the use of PHA in vivo is hard to see. Experimental evidence suggests that PHA administered intravenously to mice after irradiation produces a reduction in the number of peripheral blood and marrow cells.

The close correlation between the viable cell count and the degree of activity in the lymphocyte cultures suggests that the changes induced by PHA are independent of the number of white cells present in culture for a wide range of numbers. This does not hold true for the leucocyte cultures, but the differences in these cultures are probably related to the varying numbers of granular cells.

Response of Lymphocytes to Penicillin: Comparison with Skin Tests and Circulating Antibodies in Man

The peripheral blood lymphocytes of man respond to a variety of stimulants in tissue culture, and undergo changes in structure including enlargement and mitosis. Non-specific stimuli such as phytohaemagglutinin, as well as specific antigens such as tuberculin, to which the cell donor has been sensitized, may evoke these changes1,2.

Although the lymphocyte stimulation test has been described as a measure of sensitization to penicillin2, this test has not been correlated with any other immunological parameters of penicillin sensitivity. An extremely sensitive haemagglutination technique has been developed which is

capable of detecting as little as $10^{-4} \ \mu g/ml$. of IgG penionloyl specific antibody in human sera3. Using this test, antibodies of 19S (IgM) and 7S (IgG) molecular classes have been detected in all of fifty-four patients completing recent therapy with penicillin, although the significance of these antibodies is not known³. On the other hand, antibodies which sensitize skin and are detected by direct skin tests and passive transfer tests have been implicated in the pathogenesis of anaphylactic reactions to penicillin. In more than twenty patients with anaphylactic reactions to penicillin, skin-sensitizing antibody was detected when tests with penicillin or its degradation products were carried out shortly after the reaction had subsided4-4. In contrast to the significance of immediate skin test reactions in anaphylaxis, the significance of delayed skin test reactions to penicillin which reach a maximum at 48 h is unknown. Positive delayed skin tests to penicillin have been reported in 5.5 per cent of patients who have not had allergic reactions to the drug7

With such techniques and skin test materials available, we considered that correlation of the in vitro lymphocyte response to penicillin with the presence of measurable anti-penicillin antibodies should be investigated. Twentysix persons were tested for immediate and delayed skin reactivity to penicillin. Blood was drawn simultaneously for haemagglutinating antibody titres and lymphocyte cultures. The subjects formed three groups: (a) fourteen patients with a history of an episode clinically compatible with an allergic reaction following penicillin therapy; (b) nine persons with no history of allergic reactions following penicillin therapy; and (c) three persons who claimed never to have been exposed to therapeutic doses of the drug. Two subjects in the first group were studied on

two occasions at least 3 weeks apart. Skin tests were performed with 0.02 molar penicillin @ (approximately 10,000 U/ml.) and penicilloyl-polylysine, a multivalent hapten in which the carrier molecule is a polylysine of about twenty lysine residues in a molecule

and which carries approximately thirteen penicilloyl The concentration used was 6×10^{-8} molar calculated as penicilloyl. The skin tests were carried out as described earliers, except that commercial solutions of penicilloyl-polylysine were used. Reactions were read after 15 min and 48 h. The haemagglutination test was also performed as described earlier3. Cultures (4 ml.) containing 3×10⁶ peripheral blood lymphocytes were incubated for 5 days in the presence of 100 U of penicillin G. The cellular response was compared with that in negative control cultures containing no penicillin and positive control cultures containing phytohaemagglutinin.

The results are summarized in Tables 1 and 2. Table 1 shows that the ten patients with immediate weal and flare skin test reactions to either penicillin or penicilloylpolylysine all showed a positive lymphocyte response. This was indicated by an increase of at least 5 per cent of reacting cells (large cells plus dividing cells) compared with the percentage of such cells in negative control cultures. No subject with negative immediate and negative delayed skin tests gave a positive lymphocyte response. The cells of one subject (Table 1, patient 10) who had never experienced an adverse reaction to penicillin, but who had a positive immediate skin test, reacted to penicillin in vitro. Only ten of the fifteen subjects listed in Tables 1 and 2 with a history of a reaction following penicillin therapy had positive immediate skin tests and lymphocyte responses. Five of the fifteen gave no objective evidence of penicillin allergy by any of the three tests. The cells of all subjects responded normally to phytohaemagglutinin.

Three of the twenty-six subjects had a delayed skin test reaction to penicillin. In these patients, the delayed skin tests did not show a constant correlation with the in vitro lymphocyte response, in contrast to the usual positive response to tuberculin of cells cultured from subjects demonstrating delayed hypersensitivity to tuber-

culin. Two of the three delayed reactors had negative immediate skin tests and negative lymphocyte responses at the time of the initial tests (Table 2). When re-tested 3 months later one of these two patients showed a marked decrease in the intensity of the delayed skin reaction, and had also developed a positive immediate skin test to penicilloyl-polylysine. Lymphocyte cultures performed at this time showed a stimulatory effect with penicillin. The third patient with delayed sensitivity had a positive lymphocyte response when first seen despite a negative immediate skin test. Five weeks later, after receiving $1\cdot2\times10^6$ U of penicillin, he had developed a strongly positive immediate weal and flare reaction to penicilloyl-polylysine. This patient had had local swelling 48 h after injection of penicillin 1 yr before the initial tests.

One explanation for the association between weal and flare skin test reactions and positive in vitro lymphocyte responses is that peripheral blood lymphocytes may produce skin-sensitizing antibodies in certain patients allergic to penicillin. The one case in which there was a temporal discrepancy between lymphocyte stimulation and skin sensitizing antibody (Table 2, patient 1) may simply represent a greater sensitivity of the culture technique compared with the skin test in detecting the presence of small numbers of antibody-producing cells. It may also be merely a fortuitous association, the development of lymphocyte responsiveness slightly preceding the appearance of skin-sensitizing antibody, but representing an entirely separate immune mechanism.

In preliminary studies, using fluorescent techniques, we have been able to demonstrate IgG, IgM and IgA within lymphocytes from patients with positive immediate skin tests when cells were cultured in the presence of penicillin. These studies also indicate that such cells show specific binding for penicillin. Others⁸ have already demonstrated the production of specific penicilloyl-antibodies by lym-

MICROBIOLOGY

Virus-like Particles in Blood Lymphocytes in Acute Marek's Disease

During a preliminary survey by electron microscopy of blood from eases of acute Marek's disease in chickens, virus-like particles were observed within cytoplasmic vesicles of lymphocytes. The experimental disease was induced by the intraperitoneal inoculation into day old chicks of a commercial broiler breed of heparinized whole blood obtained from cases of acute Marek's disease from a field outbreak in November 1965. Blood was withdrawn from the wing vein of eight of these experimentally injected birds which showed the paralysis or tumours typical of the disease and from one bird which had been similarly injected but showed no signs of involvement. The birds were killed and the diagnosis was confirmed by macroscopic and histological examinations. As control material, blood was obtained from six uninjected and apparently healthy birds of the same breed which had been reared apart from the treated group. Blood was also obtained in a similar manner from two broilers from the Lebanon which were affected with spontaneous acute Marek's disease and from three spontaneous cases of classical Marek's disease occurring in Brown Leghorns from the stock at the Poultry Research Centre. Leucocytes were prepared for electron microscopy by a method based on that of Anderson¹.

Virus-like particles were observed within cytoplasmic vesicles in a small proportion of lymphocytes from five of the eight birds affected with experimental acute Marek's disease and in both the spontaneous cases from the Lebanon. Similar particles have been found in lymphocytes from one of the six uninoculated control birds and in the asymptomatic chicken which had been inoculated with whole blood which subsequently proved to be infective. In the latter two cases, however, not more than one virus particle in each vesicle section was seen,

whereas vesicle sections containing clusters of up to twelve particles were present in lymphocytes from some cases of animals with the experimental disease (Fig. 1). Particles were not found in blood lymphocytes from spontaneous classical Marek's disease. The particles were morphologically similar to the RNA viruses associated with the avian leucosis/sarcoma group of diseases. They were oval, averaged 88 mu in the longest axis and consisted of a dense central nucleoid of about 40 mu diameter surrounded by a double coat of protein. They seemed to be formed by budding from cytoplasmic membranes. have been detected only in lymphocytes; they have not so far been found in a more restricted survey of infiltrated nerves, gonadal and renal tumours.

Acute Marek's disease is highly infectious so that without more elaborate isolation facilities than those available in this experiment, accidental infection of the controls cannot be excluded. The presence of particles in the greater proportion of cases of acute Marek's disease and the greater number of these particles in diseased cases as compared with the controls, however, together with the known infectivity of whole blood in the disease, suggest that the virus particles may be in the condition. On the other hand, the presence of virus particles does not necessarily mean that they are the causal agents; there are several reports in the literature of particles of similar morphology to the avian tumour viruses occurring in tissues from apparently healthy, normal chickens, chicken embryos or tissue cultures which originate from apparently normal embryos2-6. They are usually taken to signify latent infections with avian tumour viruses or related non-pathogenic viruses. Particles of similar architecture have been seen, in the nerve of Remak of an embryo which was negative in the resistance inducing factor (RIF) test. This suggests that they could have been the RIF negative⁸ Marek's disease agent. Considerable evidence has recently been presented indicating the association of a virus resembling herpes with acute Marek's disease. The exact role of this DNA virus and the possible involvement of other viruses in the disease are not yet certain, so that the observation of another virus-like particle in the cytoplasm of intra-vascular lymphocytes from cases of acute Marek's disease is of interest.

Classical Marek's disease has always been regarded as difficult to transmit. Confusion between this condition and lymphoid leucosis undoubtedly invalidates some earlier claims of success, while other positive results may have been with the acute form, which in our experience is certainly not a new manifestation of the disease.

Fig. 1. Electron micrographs showing intracytoplasmic vesicles containing virus-like particles in blood lymphocytes from cases of experimentally transmitted acute Marek's disease.

Transmission of the classical form using material containing intact cells has recently been reported10, but an associated infectious agent has not yet been characterized. It may be that classical and acute Marek's disease are aetiologically distinct.

Emetine and Blocking Excystment of Schizopyrenus russelli Cysts

Yorke and Adams1 have found that 5 per cent emetine fails to kill the cysts of Entamoeba histolytica in 30 min This communication deals with the effect of emetine in preventing excystment of Schizopyrenus russelli and the cysticidal action of the drug in conjunction with sodium lauryl sulphate.

Cysts of S. russelli produced in monobacterial culture with Escherichia coli were used. Viable sterile cysts, free from bacteria, were obtained by the method of Singh et

al.2. Aqueous extract of E. coli and 2 per cent L-glutamic acid (pH 6.0) were used as excystment agents³

Cysts of S. russelli, treated with emetine (1,000 µg/ml.) together with one of the excystment agents, failed to excyst in 24-48 h. When emetine was removed by washing the cysts in double distilled water, there was nearly 100 per cent excystment in the presence of E. coli extract. There was a progressive increase in the percentage of excystment when concentration of the emetine in the excystment agent was reduced. With 62.5 µg/ml. of emetine, a concentration not amoebicidal for S. russelli4, excystment resembled that of control untreated cysts. Cysts, treated with emetine (1,000 µg/ml.) together with excystment agents, were morphologically normal. These results indicate that emetine blocks the action of excystment agents on the cysts, without affecting their viability. Even the ninhydrin reaction of glutamic acid was inhibited by emetine (1,000 µg/ml.). As Dhar pointed out⁵, there seems to be a weak interaction between emetine and

glutamic acid when they are in solution, even though

they can be separated chromatographically.

Cysts treated with 15.6 µg/ml. of aqueous solution of sodium lauryl sulphate for 48 h readily excysted in extract of E. coli after the removal of sodium lauryl sulphate. When they were treated with the same concentration of sodium lauryl sulphate plus emetine (1,000 µg/ml.) for 48 h and washed with distilled water, there was no excystment in the presence of E. coli extract. Staining with eosin showed the cysts to be dead. The protoplasm of these cysts together with the inner cyst wall was very much shrunken. Thus sodium lauryl sulphate seems to make the cyst wall permeable to emetine. This approach to the curing of dysentery by making the cysts permeable to amoebicides by the use of surfactants has not yet been attempted, but it may be applicable to the elimination of cysts of E. histolytica in human carriers.

Leukin, a Bactericidal Agent from Rabbit Polymorphonuclear Leucocytes

The term leukin was proposed almost 60 years ago to denote a class of granulocytic antibacterial agents selectively active against Gram positive bacteria1. During the past decade, sufficient progress has been made to indicate the potential significance in host defence of such bactericidal agents. Knowledge of the chemical nature of a potent leukin present in rabbit neutrophiles first emerged in 1956. On the basis of high arginine (17 per cent) and low lysine (4.5 per cent) content, this leukin was considered to be a protamine derivative². It was subsequently shown that bacteria undergoing dissolution within developing inflammatory lesions become progressively coated with a highly basic arginine-positive substance³, which is probably delivered to the bacterial surface during phagocytosis. Leucocytic granules, which contain the bulk of the bactericidal agent4, appear to fuse with phagocytic pouches containing bacteria and to release their contents into these pouches during degranulation^{5,6}. highly localized intracellular delivery system is probably most important because highly basic proteins or polypeptides would be neutralized and rendered less effective in an extracellular milieu. It is interesting that granulocytes from patients with an X-linked granulomatous disease seem to phagocytose normally but do not kill ingested bacteria7. The leucocytic defect is apparently related to improper degranulation rather than to a deficiency in the bactericidal agents.

This communication describes a further purification and characterization of the leukin obtained from rabbit granulocytes. Adult rabbits received intraperitoneally 200 ml. of physiological saline containing 10 µg of endotoxin. Eight hours later, each animal received by the same route 150 ml. of saline containing heparin. The granulocytes, of which 95 per cent were polymorphonuclear, were washed, pooled and subjected to the extraction and purification procedure described earlier2.

Some of the final product (6 mg) was dissolved in 6 ml. of 0.03 molar acetate buffer, pH 4.0, and fractionated on

'Sephadex G-25'. The leukin preparation and the 'Sephadex' fractions of these were adjusted to pH 6.0 or 7.6 before antibacterial assay. Graded amounts of test fractions were added to tubes containing 0.1 ml. of 5 per cent dextrose and 0.4 ml. of a 10-2 dilution of an 18 h broth culture of the desired bacterium (about 10⁶ bacteria). Phosphate buffered saline at pH 6.0 or 7.6 was added to a final volume of 1.5 ml. After 1 h at 37° C. 5 ml. of nutrient broth was added and incubation continued for 10 h. Antibacterial potency was measured photometrically by the capacity of test fractions to inhibit outgrowth of inoculae2.

An agar slant-tube method was also used to assay bactericidal activity. Graded amounts of test fractions were added to 18×150 mm tubes (in triplicate) containing 0.1 ml. each of 5 per cent dextrose and nutrient broth and 0.3 ml. of 2×10^{-6} dilutions from 5 h broth cultures (about 100 bacteria). Buffered saline at pH 6.0 or 7.6 was added to a final volume of 1.0 ml. and the tubes incubated for 1 h at 37° C. A sample of 7 ml. of molten nutrient agar (at 47°-48° C) was pipetted rapidly into each tube. Tubes were immediately positioned at a shallow angle, cooled and incubated at an inclined angle for 16-20 h at 37° C. Colonies were counted over opaque white light to determine the percentage kill as compared with controls.

The bactericidal potency of the leukin at alkaline pH was quite different for the bacterial strains tested (Fig. 1). The concentration of leukin which killed 50 per cent of the Micrococcus aureus inoculum was only one-tenth of that required to kill a similar number of cells of Escherichia coli at pH 7.6. This difference in susceptibility was not obtained at pH 6.0, in which case the susceptibility of

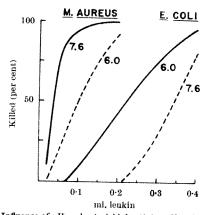

Fig. 1. Influence of pH on bactericidal activity of leukin (0.01 per cent) as observed against M. aureus and E. coli. The agar slant-tube method was used. ——, Optimum pH for activity against each strain.

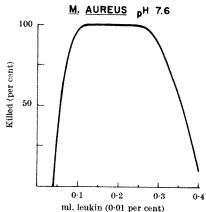

Fig. 2. Reversal of bactericidal activity in excess of leukin as observed in the slant-tube assay.

E. coli approached that of the Gram positive strain. This pH effect was also noted with the 0901 strain of Salmonella typhosa which likewise proved to be more

susceptible to leukin at acid reaction.

In the agar slant tube assay, a type of "prozone" was observed at higher concentrations of leukin (Fig. 2). This inoculum-sparing effect seemingly is related to the particular methodology employed. Because the highly basic leukin is probably fixed onto the bacterial surface, as demonstrated with other basic proteins and polypeptides, the subsequent addition of acidic agar to incubated mixtures may cause a rapid displacement and neutralization of the basic polypeptides. This would permit multiplication of those bacteria not damaged during the previous incubation period.

Fractionation of the leukin preparation on 'Sephadex G-25' resulted in the separation of several peaks (Fig. 3). Each fraction was tested for bactericidal activity and only the mid-region fractions II and III were active (Figs. 4 and 5). Although much inactive material was separated (fraction I_A and I_B), the heterogeneity of the bactericidal fractions is apparent and complements the earlier finding

of electrophoretic heterogeneity2.

The arginine content of fraction II was 26 per cent, determined by the Sakaguchi method¹⁰; this represents a significant enrichment in basicity. The importance of the basic amino-acids, arginine or lysine, as determinants in the antibacterial activity of basic proteins and polypeptides is recognized.

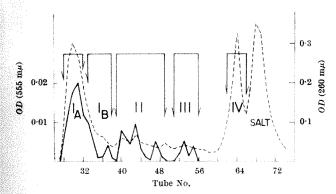

Fig. 3. 'Sephadex' fractionation of leukin. The 86×2.5 cm column contained 95 g of 'Sephadex G-25' equilibrated with saline-acetate buffer, 0-03 molar, pH 4. Elution with buffer at 75 ml/h with a tube volume of 6 ml. (---) Optical density, 260 m μ ; (----) optical density, 555 m μ . Biuret readings were taken on 1 ml. samples.

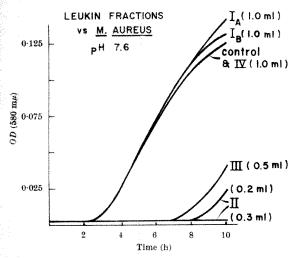

Fig. 4. Antistaphylococcal activity of 'Sephadex' fractions determined by broth outgrowth method. Values in parentheses represent amounts of designated fractions tested separately in each experiment.

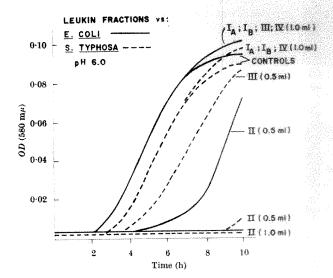

Fig. 5. 'Sephadex' fractions tested against two Gram negative species as measured by inhibition of outgrowth in broth. The values in perentheses represent amounts of designated fractions tested separately in each experiment.

The difference of susceptibility between Gram positive and Gram negative bacteria at alkaline pH suggests that the leukin preparation contains more than one kind of antibacterial agent. The other known antibacterial agents present in polymorphonuclear leucocytes are histone and lysozyme. The low lysine content of leukin and the absence of antibacterial activity in the excluded 'Sephadex' fraction I_A-I_B, argue against the presence of histone. Lysozyme was not detected by standard assay. Thus the leukin preparation appears to contain one type of bactericidal agent, namely the protamine-like proteins or polypeptides originally described².

The relationship of leukin to the bactericidal agent phagocytin¹¹ cannot be ascertained in the absence of chemical data about the latter. The many common descriptive properties of leukin and phagocytin, however, indicate a strong resemblance; they seem to be the same substance. The observation that phagocytin resists pepsin digestion is in keeping with the known resistance of protamines to hydrolysis by many proteolytic enzymes, including

pepsin 12,13

It was suggested initially that leukin derived from the cell nucleus, but the subsequent studies of Cohn and Hirsch' demonstrated that the bactericidal activity originated in the "lysosomal" granules. They found that little or no activity was released from granules at pHs greater than 5. This dependency on acid pH for release of potent bactericidal activity from whole granulocytes was observed in the earlier leukin study.

Seegers and Janoff isolated from granules of the rabbit neutrophil an arginine-rich fraction (MCF) which caused the rupture of rat mast cells¹⁴. The leukin preparation was subjected to 'Sephadex' fractionation as used by these authors and bactericidal activity was eluted in the same region as MCF. A comparison of the known characteristics of leukin and MCF indicates that they are closely related, if not identical. Both agents have high arginine and low lysine contents, behave similarly in gel filtration, show cationic heterogeneity in electrophoresis and are heat stable.

Zeya and Spitznagel have shown that the bactericidal proteins extracted from granules of the guinea-pig neutrophil contain large amounts of lysine as well as arginine¹³. Apparently this antibacterial agent is different from rabbit leukin and more closely related to the arginine rich histones^{13,16}. Studies are in progress to elucidate the structure and mode of action of the bactericidal leukins from rabbit and human granulocytes.

This investigation was supported by a Public Health Service research grant from the US National Institutes of Health.

Atypical Menaquinone Pattern in a Strain of Staphylococcus aureus

KORMAN¹ described the production of coagulase positive and pleiotropic, coagulase negative mutants from a strain of S. aureus, NCTC 8511 (propagating strain 53 of the International Phage Typing series), by ultraviolet irradiation and selection on tellurite glycine agar. Amino-acid, amino sugar and teichoic acid compositions of the cell walls of the Korman parental strain (NCTC 8511) and of the mutants have also been published^{2,3}. We have now determined the menaquinone content of these strains.

Studies on the distribution of menaquinones (MK) in Micrococcaceae4 have revealed characteristic patterns associated with each of the accepted species Staphylococcusaureus, Micrococcus luteus and M. roseus, and the classification of certain strains of Micrococcus proposed by Rosypal et al.5 has also been substantiated by MK patterns. Earlier work has also shown that the parental Korman strain has an MK pattern different from that of any other staphylococcus or micrococcus so far examined. It contains, in addition to other isoprenologues, MK-4 and MK-5, neither of which had previously been extracted from bacteria.

This communication describes a comparison of the MK pattern shown by twenty strains of S. aureus with those of four cultures of S. aureus, NCTC 8511. from different sources, including the Korman parental strain, and four of the strains described as mutants by Korman¹. All strains were grown on nutrient agar plates (blood-agar base: Oxoid, Ltd.) and quantities of between 2 and 5 g wet weight of cells were collected; the MKs were extracted and the isoprenologues separated and identified as described by Jeffries et al.4.

Table I shows the MK patterns (percentage of individual isoprenologues) of the strains studied and, for comparison, the mean and range values obtained with twenty other strains of S. aureus varying in antibiotic sensitivity patterns and bacteriophage types. The MK patterns of the twenty different strains of S. aureus and of three out of four cultures of NCTC 8511 are similar, with MK-8 as the chief and MKs-9 and -7 as the minor isoprenologues. A different and distinct MK pattern was shown by both the Korman parental strain of this organism and the coagulase positive mutant (HS 635) derived from it; on bacteriophage type, however, both these strains were indistinguishable from the three strains of NCTC 8511 from other sources. In a personal communication Dr Korman has stated that she received her culture of NCTC 8511 from Dr M. L. Morse in 1958 and that the mutant HS 635 was produced early in 1959. Both the Korman parental NCTC 8511 and HS 635 now have a common MK pattern, possibly supporting their relationship; this pattern is, however, different from that of the culture NCTC 8511 which we received from Dr Morse in 1967. This suggests that either the MK pattern of the Korman parental strain changed before the mutant HS 635 was produced from it, or that the MK pattern of both strains altered subsequently. The Korman strains were received as agar stab cultures, but we are unaware of either the composition of the media used for their maintenance or the frequency with which they were subcultured before we received them. In our laboratory, the MK pattern of the Korman parental strain has, like those of other staphylococci and micrococci, remained constant after several transfers on Lemco agar.

The coagulase negative strains (HS 968 and HS 1160) contained only MK-8 and MK-7. The isoprenologue ratios were, however, different in the two strains and the MK patterns resembled those previously found in other coagulase negative staphylococci. From HS 968, described as a ccagulase negative mutant derived from the coagulase positive mutant (HS 635), Korman¹ claims to have isolated a single colony of a revertant mutant (HS 1159), which she regarded as identical with the parental strain (NCTC 8511) in all respects apart from pigmentation. Table 1 shows that HS 1159 produced an MK pattern similar to

^{*}MK totals and percentages for the 20 strains of S. aureus are given as means, with ranges in parentheses. The MK totals and percentages for the other strains are the means of replicate assays, with standard deviations in parentheses.

† A further ten strains of S. aureus examined after alkaline digestion gave a similar MK pattern.

MK-8 was the principal isoprenologue in all assays but, because MK-9 and MK-8 were inseparable in 3 out of 13 assays, a single value is given for the combined isoprenologue fraction. In assays where MK-9 was separated it formed a mean 6 per cent of the total MK.
MK, Menaquinone; ND, not detected; NCTC, National Collection of Type Cultures, London, England.

that of most S. aureus strains and therefore different from that of the Korman parental strain. Bacteriophage typing patterns revealed six differences in reactions between the alleged revertant (HS 1159) and the parental strain. Further evidence that the "revertant" is unrelated to, and was therefore probably not derived from, NCTC 8511 is provided by studies in which NCTC 8511 was found to be lysogenic for two phages, both of which lyse HS 1159. Furthermore, HS 1159 carries a phage with a different host range from either of the phages carried by NCTC 8511.

Menaquinone patterns have thus revealed a difference, not detectable by bacteriophage typing, between a strain of S. aureus used in genetical studies and three other cultures of the same strain. The atypical MK pattern of the Korman parental strain, in addition to being different from that of thirty other strains of S. aureus, contained MKs not previously encountered in forty-nine strains of staphylococci and forty-one strains of micrococci. We do not know why the parental strain has shown a changed MK pattern. The MK pattern of the same strain from other sources and those of the other strains of S. aureus have remained stable on subculture, and also after freezedrying. The MK patterns of a wide variety of micrococci have shown similar stability.

We thank Mrs E. Asheshov, of the Central Public Health Laboratory, Colindale, London, for the bacteriophage studies and for helpful advice on their interpretation. We also thank Dr M. L. Morse and Dr A. C. Baird-Parker for supplying cultures of NCTC 8511, and Miss Barbara Cook for assistance with the menaquinone assays.

Lack of Resistance of Adult Mice to Erythrocyte-borne **Bittner Virus**

BITTNER virus, the classical mouse mammary tumour virus (MTV), can be detected in bioassays of various organs and tissues of infected mice including mammary tissues and erythrocytes1-3. We have shown that the final result of the administration of MTV-carrying RBC or of mammary tissue extracts to young hosts is identical: namely, the production in test mice which are free from MTV of mammary nodules and tumours containing electron microscopically visible B particles. The MTV in these two tissues differ, however, in several respects^{2,3}. MTV activity in mammary tissues (M-MTV) is itself associated with B particles, but such particles do not seem to be associated with RBC which bear MTV activity (R-MTV). Resistance to tumorigenesis of adult animals following oncogenic viral administration is well known⁴. Several investigators have demonstrated that adult mice are more resistant than young ones to mammary tumour development after administration of MTV^{5,6}. We have recently suggested that this resistance in adult mice of the BALB/c strain is systemically mediated. Dux and Mühlbocks,

however, have proposed that both host age and tissue age are involved in the resistance of older mice to MTV. R-MTV has been shown to precede the appearance of M-MTV in naturally infected mice, and so it was thought possible that a failure in R-MTV production which followed administration of M-MTV to adult mice might account for the low incidence of mammary nodules and tumours. We have now compared the effects of administration of the two forms of MTV to mice of different ages.

In all experiments BALB/cfC3H/Crgl (C+)served as MTV donors and syngeneic MTV free BALB/ cCrgl (C−) female mice of different ages were used to Whole blood and test the effect of R-MTV or M-MTV. washed intact or haemolysed erythrocytes from C+ mice served as the source of R-MTV. The source of M-MTV was cell free extracts of lactating mammary tissues from C+mice. The methods for preparation of R-MTV and M-MTV are similar to those reported previously7,9 except that the diluent contained 0.005 molar magnesium chloride; the latter seems to have a stabilizing effect on MTV. Both R-MTV and M-MTV preparations were administered to C - mice intraperitoneally. The effect of MTV on hosts was determined by the noduligenic assay for the detection of MTV1,10. Data are reported both in terms of percentage hosts with nodules, and incidence of nodules in each nodule-bearing animal (unpublished data indicate that only the former is correlated quantitatively with the dose of virus).

Experiments 1 and 2, summarized in Table 1, show the effect of R-MTV and M-MTV in mammary noduligenesis in immature and mature (8 week and older) C-mice. Two sources of R-MTV were employed in these experiments, and both induced mammary nodules in mice of all ages, the incidence varying between 86 and 100 per cent. Many hosts in most of these groups developed mammary tumours as well. No statistically significant differences were observed in the percentage of test mice with nodules among different age groups. In contrast, M-MTV, which produced a high incidence of nodules in the 3 week old group, was much less effective in the 18 week old group. The percentage of mice with nodules in the older group treated with M-MTV was significantly lower $(P \leq 0.001)$ than that in all other groups in experiments 1 and 2.

* With the exception of one group of 52 week old parous females (in exp. 1b), all hosts were virgin females.
 † Mean ± S.E.M. number of nodules in nodule-bearing bosts.

The experiments reported in Table 2 were designed to determine the presence or absence of R-MTV in mice inoculated with M-MTV. Whole blood from individual donors was collected immediately before and at the end of the assay period and was administered to C- mice. The results (Table 2) clearly show that R-MTV formation results from M-MTV administration in mice of both age groups and that the animals carry infectious virus throughout the assay period.

These results substantiate our previous suggestion 2,3 that R-MTV differs from M-MTV in its biological behaviour. R-MTV can induce mammary nodules in mice of all ages whereas nodules and tumours induced by M-MTV are primarily restricted to mice which are immature, that is, relatively immunologically incompetent11 at the time of virus administration. These results also show that tissue

Whole blood from individual donors was injected into female C - hosts 3 weeks of age.

age is unimportant in the development of nodules and

tumours resulting from R-MTV administration. Although exogenous R-MTV administration results in nodule and tumour development in adult mice (supposedly immunologically competent), endogenous R-MTV appearing after M-MTV administration was incapable of producing this effect in adult mice. That R-MTV induces nodules in hosts of all ages is perhaps not surprising in view of the recent evidence that the viral nucleic acid of R-MTV could be associated with host H-2 antigens and not with B particle antigens³. The possibility that B particle antigens are lacking in R-MTV is also suggested by the fact that no precipitation reaction with rabbit anti-B particle antiserum is observable when RBC lysates from C + mice are used as the antigen¹². It is thus unlikely that the host immunological defence mechanisms will be operative against R-MTV (coated or associated with host H-2 proteins) which is administered to syngeneic mice of various ages. This explanation, however, cannot account for the low incidence of noduligenesis in M-MTV inoculated adult mice which produce R-MTV soon after the virus administration. A hypothesis can be suggested to explain this enigmatic situation. Because the M-MTV preparations were made from relatively old mice, they are likely to carry both viral (B particles) and associated tumour antigens, and the injection of such extracts has been shown to induce transplantation resistance against C+ mammary tumours in adult C- mice¹¹. Thus it is possible that adult mice injected with mammary tissue extracts are immunized against both these antigens, and their immunity against either or both is involved in the rejection of preneoplastic or neoplastic clones, induced by endogenous R-MTV before these clones have an opportunity to establish themselves. Tumour-specific immunity has been suggested as the reason for resistance to tumour development after infection with oncogenic DNA viruses such as the polyoma virus in adult mice13, and this immunity has also been suggested for one RNA virus-induced tumour system¹⁴. In the mammary tumour system¹⁵, like most other RNA virus systems, it is difficult to determine whether tumour specific or virus specific antigens are involved in resistance, because the virus persists in the tumours. Earlier reports have shown that although adult mice injected with a single dose of MTV extract usually fail to develop tumours, they are nevertheless able to transmit the virus to their progeny in their milk^{5,6}. R-MTV is destroyed by oral administration^{2,3} and these results therefore suggest that the older mice might be producing M-MTV (B particles). Thus antiviral antibodies may not play any significant part in these mice although some adult C- mice injected with repeated doses of MTV extracts are known to produce such antibodies¹⁶. If so, then the relative lack of noduligenesis and tumorigenesis in adult mice (with persistent viraemia) following administration of M-MTV might be the result of immunity against the tumour-specific antigens which were present in the original MTV-carrying mammary tissue extracts. This could explain the presence of viraemia along with immunity against the colonization of preneoplastic or neoplastic foci. Further electron microscopic and transmission experiments to determine the presence or absence of B particles in the mammary tissue of adult mice inoculated with M-MTV are necessary to elucidate the mechanism of resistance of adult mice to MTV-induced noduligenesis and tumorigenesis.

PATHOLOGY

Establishment of Cell Lines from Peripheral Leucocytes in Infectious Mononucleosis

Cell lines have been established in vitro from peripheral leucocytes taken from patients with leukaemia1-4, lymphomas¹ and malignant melanoma with leukaemoid reaction5. There are also two reports of cell lines derived from pre-sumably normal leucocytes^{6,7}. We have found that in infectious mononucleosis cell lines can readily be established from peripheral leucocytes.

Patients with a provisional diagnosis of infectious mononucleosis on clinical and haematological findings were referred to us from hospitals in Brisbane. Six cases with a positive Paul-Bunnell test⁸ were accepted as infectious mononucleosis (see Table 1); each had fever, sore throat and lymphadenitis and atypical mononuclear cells in the blood.

Heparinized blood was allowed to stand in a vertical tube at room temperature until sufficient plasma separated. Leucocytes from the plasma were washed twice in Eagle's basal medium containing foetal calf serum and other additives and cultivated at an initial concentration of $1.5-5.0 \times 10^6$ /ml. in 5 ml. of medium in either 25 ml. conical flasks¹⁰ or 60 mm plastic tissue culture dishes (Falcon Plastics). Cultures were incubated at 36° C in a humidified atmosphere of 5 per cent carbon dioxide in air. Partial changes were made in the fluid medium twice weekly. The cultures were examined in the living state and were maintained until proliferation was evident or

until all remaining cells were dead. As soon as the first cell line became established it was clear that in further studies the possibility of contamination with other cell lines already present in the laboratory should be rigorously excluded. Consequently, later cultural procedures were isolated as completely as possible from any other cell culture studies.

The cultures from the six patients were similar in the early stages. Within the first 2 or 3 days many of the cells in suspension died, but some successfully attached and included fibroblastic cells, large undifferentiated cells and smaller irregular cells which sometimes formed small The attached cells usually remained in good condition but were not seen to multiply. Usually after 2-3 weeks of culture, but varying with individual cultures, most smaller attached cells became slightly less irregular and detached from the vessel. In unsuccessful cultures the detached cells degenerated, but in successful cultures some remained viable as shown by very clear cytoplasm and prominent spiky extensions. Such cells were usually present in small groups; definite proliferation in a culture was indicated by unequivocal enlargement of these small aggregates. The period of culture at which this stage was reached is listed in Table 1. Once initiated, proliferation continued actively and the small aggregates of irregular cells increased in number and in size up to about 1 mm.

The three lines established (Table 1) behaved similarly in culture and resembled each other in the appearance of the viable cells; these properties so far appear to be stable. In each line two types of mononuclear cells could be identified in smears stained with Giemsa-primitive cells varying in size from 14 to 23µ with plentiful cytoplasm, and less frequent larger cells (30 to 45µ) with a more reticular nucleus. The cultured cells did not resemble characteristic atypical mononuclear cells of infectious mononucleosis and appeared to be undifferentiated haemopoietic cells.

In the conditions of culture, cell lines were established with relative ease from the blood in infectious mononucleosis; the proportion of cultures successful (3/6) was apparently higher than that obtained with leukaemic blood (2/10) or normal blood (0/13), although the number tested is small. The recent demonstration that the proportion of peripheral mononuclear cells synthesizing DNA is greatly increased in infectious mononucleosis is relevant to the tissue culture results reported here¹¹. It is probably significant that in another laboratory the proportion of successful lymphoblastoid fibroblast cultures from bone marrow was also higher in infectious mononucleosis (13/22) than in leukaemia (6/77, ref. 12). not clear, however, why the lymphoid cells grown from bone marrow in that study were dependent on the fibroblasts in the culture, while our cultures from blood grew freely in suspension.

It is most interesting, particularly because certain basic similarities between infectious mononucleosis and leukaemia have been pointed out13,14, that the lines of cells grown from infectious mononucleosis should bear a general resemblance to those from leukaemia. These results could be interpreted as suggesting similar actiology in infectious mononucleosis and leukaemia. Another possibility is that the two are actiologically distinct yet have in common the presence of cultivable cells in blood. In view of the establishment of cell lines from leucocytes in various neoplastic conditions1 and from apparently normal leucocytes^{6,7}, further studies are necessary to determine the significance of cultivable cells in blood.

Thorough virological examination of the new cell lines is essential, in view of the long suspected viral aetiology of infectious mononucleosis and of the presence of particles resembling herpes virus in several strains of cells derived from cases of leukaemia1,15 and Burkitt lymphoma¹⁶⁻¹⁸ and from non-malignant leucocytes^{6,7}. In tests made so far, no virus has been recovered from the new cell lines by inoculation of various tissue cultures. I thank Dr A. F. Knyvett, Dr A. K. Patel and Dr T. A.

MacDonald for specimens for culture and case histories, and Dr H. Smith for conducting the Paul-Bunnell tests and for discussions on the cytology of the cultured cells. Mr W. Scott gave assistance with the cell cultures.

Tumours induced by Chicken Sarcoma in Monkeys conditioned with Progesterone

REPORTS of skin and organ transplantation, as well as of tumour induction and serial passage in laboratory animals, have casually mentioned that the duration of graft survival is enhanced by pregnancy1-3; more tumours can

be induced in pregnant and adult female than in adult male rodents³. There are examples of experimental animals, unexpectedly found to be pregnant, which have been discarded from the experiment⁴ with this explanation. Furthermore, several workers have shown newborn mammals to be more susceptible to virus infection, and less resistant to skin or organ transplantation, than mature animals of the same species.

We have used monkeys to test the hypothesis that progesterone is directly or indirectly involved in the increased susceptibility of the pregnant, as well as of the newborn mammal. Our first results were encouraging. Eleven out of eleven otherwise resistant juvenile and adult monkeys, conditioned with progesterone and with demonstrated elevated concentrations of progesterone in the blood, developed large fast-growing tumours 1–3 weeks after inoculation of a chicken sarcoma (Carr–Zilber) preparation.

Data on eighteen normal monkeys which failed to develop tumours after inoculation of chicken sarcoma material^{5,6} are summarized in Table 1. Sixty-two out of sixty-five control monkeys conditioned with corticosteroid developed tumours; details have already been published^{5,6}. There was invasion of the rib cage in four monkeys, as well as metastases to the lungs in two others and to the liver in three others. In two of these monkeys, the metastatic lesions caused typical tumours when they were back passaged to chickens.

Table 1. TUMOUR INCIDENCE IN JUVENILE AND ADULT MONKEYS

	No.	Tumour incidence
Normal Adult controls Pregnant	18 2	0 2
Treated Hydrocortisone (single dose) 'Imuran' (5 days)	3 8	0 7
X-ray (155 r) 'Celestone' (daily I.M.)	3 65	3 62
Progesterone (aqueous I.M.) 'Provera' (oral)	8 I	8 1

Recently, eight juveniles (two of which were male) and two adults (five M. mulatta, four M. speciosa and one C. aethiops) were conditioned with daily intramuscular injections of 5 mg/kg of progesterone and then inoculated with the chicken sarcoma material containing 1.5×10^8 ... 12×10^8 infective viral units. All developed tumours at the site of inoculation in 8-15 days and these tumours were histologically fibrosarcomas, with, in addition to the typical fusiform cells characteristic of the tumours in newborn and corticosteroid-conditioned monkeys, large rounded cells with acentric nuclei scattered throughout. Virus was demonstrable in all these tumours by back passage to chickens (Table 2).

Table 2. CHICKEN SARCOMA-INDUCED TUMOURS IN PROGESTERONE CONDITIONED MONKEYS

Preparation	No.	Treatment	Tumours	Latency
Pregnant mulatta Normal adult mulatta	2	None 'Provera' (oral)	8 3	7–15 days 18 days
Speciosa mulatta	3) 5;	Progesterone (I.M.) 5 mg/kg/day	24	7-21 days

Two females of M. mulatta in the third trimester of pregnancy were inoculated with a chicken sarcoma mince containing 20×10^8 and 25×10^8 infective viral units as described before^{5,6}. Each developed three large fast-growing tumours at the sites of inoculation. In the first animal, the three tumours regressed and disappeared 3-4 weeks after biopsy and parturition; one tumour of the second animal was removed 7 days after parturition for histology and for viral recovery examination; at that time, the other tumours had ceased to grow and daily intramuscular injections of progesterone were started. In 14 days the tumours had attained proportions much larger than previously, and a larger tumour recurred at the site of excision (Table 2).

An adult M. mulatta female was given five 10 mg tablets of 'Provera' on each of 2 days before the inoculation of 20×10^8 infective viral units into three sites. Tumours developed at these sites in 5 days after inoculation (Table 2).

In control monkeys receiving daily corticosteroids, the body weight at first reflected a progressive loss, and several months later reached a plateau at a low level, but animals receiving daily progesterone gained weight and maintained these weights. Incisions made for the removal of tumours or for biopsy in the monkeys treated with progesterone healed in half the time required in corticosteroid treated animals.

In ten animals injected or fed large doses of progesterone, there were no respiratory infections, diarrhoea or febrile illnesses. This contrasts with the monkeys conditioned with corticosteroid, of which 25-40 per cent developed one or the other of these conditions. The decrease in the number of lymphocytes in the circulation, seen in the monkeys conditioned with corticosteroid, was also observed in the monkeys conditioned with progesterone.

The concentrations of progesterone and 4-pregnane-20α-ol-3-one in the plasma were measured in some of these conditioned animals by the double isotope dilution technique (personal communication from Gandy) (Table 3). Concentrations of progesterone were 80–230 times greater than in normal male and female monkeys. Values in two pregnant monkeys and an 11 day old infant were considerably less than in treated animals, and were less than those seen at mideycle of non-pregnant adult females.

Monkeys injected or fed daily with progesterone, as well as pregnant monkeys, developed tumour's at the site of inoculation of the Carr-Zilber strain of the Rous chicken sarcoma material. Concentrations of progesterone and one of its isomers were found to be generally greater in the susceptible monkeys than in the resistant monkeys. Progesterone is known to be a precursor of the adrenocorticosteroids, but it is not yet certain whether progesterone acts as an immunodepressant indirectly through the stimulation of adrenocorticoids or directly on some phase of antibody production, release, transport or specific activity. The absence of side effects in these monkeys at the doses used in this experiment, while healing was faster and all the monkeys gained in weight, suggests that progesterone can be preferable to corticosteroids for certain clinical conditions. This substance may control the immune response, for example, in pregnancy (from the maternal as well as from the foetal point of view).

Table 3. PLASMA PROGESTERONE CONCENTRATION IN MONKBYS

.	No.	Progesterone	20a-Hydroxy- progesterone μ g/100 ml.	Dose
Normal		0.15 0.01	0.04.0.08	
Male Female	3	0.17-0.21	0.04-0.07	
Preovulatory	3	0.10-4.0		
Midcycle	$\frac{2}{2}$	7.0-13	0.49-0.63	
Premenses	2	$1 \cdot 23 - 1 \cdot 32$	0.07-0.09	
Infant (11 days)	1	0.30	0.07	
Pregnant Third trimester	2	0.44-0.62	0-21-0-23	
Treated Female	4 1	14·8-26·42 26·94	3·08-10·5 5·63	5 mg/kg
Male	T	20'94	9.09	5 mg/kg

The inadequately explained susceptibility of the pregnant and newborn mammal to pathogens and the weakened resistance to skin grafts, organ transplants and tumour passage now seem to embrace the concept of elevated progesterone concentration in these animals.

This work was supported by a US Public Health Service grant. We thank Dr H. M. Gandy for measuring the plasma progesterone, Dr S. Sternberg for his opinion in the evaluation of the pathological sections, Mrs Ivy Munroe for discussions, and Mr T. Kung, Miss J. Waxman, Miss

P. Rullan, Mr S. Lopez and Mr G. Castro for technical assistance.

PHYSIOLOGY

Ammonia and the Regulation of Acidity in Human Eccrine Sweat

THE acidity of human eccrine sweat has been reported to be regulated by the lactate system^{1,2}, by amino-acids³ and by the bicarbonate system⁴. We have examined correlations between acidity and electrolytes of eccrine sweat.

Sweat was collected from nine men and two women from January to May 1966, with intervals of one or more weeks between collections from each subject.

On the day before each experiment, the subject cut his fingernails, shaved both arms with an electric razor and washed each arm for 3 min with a surgical brush using tap water and a solid detergent ('Vel', Colgate-Palmolive; this material is neutral in reaction and non-allergenic for our subjects). On the day of the experiment, the subject washed the arms for 3 min with warm tap water and detergent and then rinsed the arms with running, warm tap water.

The hot room was kept at DBT 40° C, WBT 21° C. After walking on a level treadmill for 15 min at 5.6 km/h (men) or 4.8 km/h (women), the subject rinsed both arms with demineralized water. They were dried gently with towels previously boiled in distilled water and oven dried. The subject donned elbow length bags (vinyl plastic wet dressing Bunyan bag, National Carbon Co.) secured with elastic bands 5 cm wide. Evaporative loss of water from inside was 1 per cent/h. The subject again walked on the treadmill for 80 min, stopping every 15 min for 5 min for the drainage of sweat from the bags. Considerable care was taken to obtain "pure sweat", that is, fluid free of particulate matter when viewed at a magnification of 430.

The sweat was centrifuged at 2,980g for 15 min at 25° C. If the supernatant was still turbid, it was frozen, thawed and recentrifuged; if "pure", it was analysed immediately or frozen at -20° C. Repeated freezing and

thawing had no effect on pH or solute concentrations.

Analyses were: sodium and potassium by flame photometry^{5,6}, chloride with Cotlove titrator⁷ (American Instrument Co., Silver Spring, Maryland), lactate by colorimetry⁶, total nitrogen, ammonia and urea by nesslerization after appropriate acid digestion, aeration or treatment with urease^{9,10} and amino-acids by the method of Spackman, Stein and Moore¹¹ (Beckman Co., Pasadena, California). Hydrogen ion concentration at 25° C was measured with a glass electrode^{12,13} (Expandomatic, Beckman) calibrated at pH 4·01 with phthalate buffer and at pH 6·86 with phosphate buffer.

Values for pH ranged from 4.70 to 7.99, with a mean of 6.40 (Table 1). Variation was much less within individuals than between them.

Table 2. Correlations between pH of human ecorine sweat and concentrations of electrolytes (n=33)

Item	Units	Correlation coefficient with pH
NH ₃	m.equiv./l.	0·56
Lactate	mmoles/l.	0·25
K	m.equiv./l.	0·30
Cl	m.equiv./l.	0·40
Na	m.equiv./l.	0·48

The highest coefficient of correlation (-0.56) was found between pH and ammonia (Table 2). Positive correlations were found between pH and sodium, chloride, potassium and lactate. As the acidity increased, the concentration of ammonia increased and those of sodium and chloride decreased.

Other correlations with pH and ammonia were probably autocorrelations. With increasing rates of sweating ammonia concentration decreased, the sweat became more alkaline, and osmolality increased. Thus there was a good correlation among these three measurements.

Although there are substantial differences between individuals, factors controlling the acid-base balance in sweat should appear in all subjects. By analogy with urine, several possible buffer systems might be considered for sweat. These include phosphate¹⁴, lactate¹⁴, bicarbonate⁴, amino-acids³ and ammonia¹⁵.

Inorganic phosphate cannot contribute. One remarkable feature of sweat is that specimens collected as described contain virtually no phosphorus, inorganic, acid hydrolysable or bound.

Lactate is unlikely to be important in the acid-base balance of sweat. Its pK is 3.9, and so its effective buffer range is beyond the range of pH seen in our specimens. Furthermore, lactate showed only a poor correlation with pH.

The bicarbonate system might be operative in the alkaline range, as suggested by Kawata⁴. Seven of thirty-three specimens were alkaline, thus agreeing with Kawata⁴ but not with Foster¹⁵, who stated that human sweat is always acid, cat's paw sweat alkaline. Dissociation curves tor carbon dioxide in the P_{CO₂} range of 20-130 mm of mercury were studied in six specimens. The plots of P_{CO₂} against dissolved CO₂ were linear, not curvilinear as they would be for a bicarbonate system. They ran

parallel with but about 2 mmoles of $\rm CO_2/l.$ higher than similar points for water. Carbamino compounds could account for this difference.

We confirm reports by others that human sweat contains free amino-acids¹⁶, 18. Twenty-three different aminoacids have been detected (Table 3). In order of highest concentration Coltman, Rowe and Atwell¹⁷ listed citrulline, serine and glycine. Hadorn et al.18 found the order to be serine, glycine, ornithine and alanine. We found three amino-acids above 0.4 mmoles/l.: serine, alanine and glycine. Titration curves of sweat concentrated ten-fold by freeze drying in vacuo18 had inflexion points at pH 2.6, 3.2, 3.4, 3.7, 3.8, 4.2, 4.5, 9.4, 10.4 and 11.5. Some of these might be associated with amino-acids. human sweat regularly contains amino-acids in concentrations great enough to affect the acid-base balance.

The correlation between ammonia and acidity was good in thirty-six specimens as shown by the regression equation for Fig. 1. With a pK of 4.8 the ammonium-ammonia buffer system has an effective range of about pH 3.8-5.8. Our highest concentrations of ammonia were from 5 to 8 m.equiv./l., occurring at pH values of less than 6. At larger pHs the concentration of ammonia was usually 3 m.equiv./l. or less. We accept the view20 that, like the kidney, the sweat gland can synthesize ammonia.

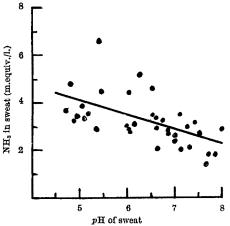

Fig. 1. The total ammonia concentration of thirty-six specimens of human eccrine sweat compared with the pH at 25° C. The regression line, calculated by the method of least squares, is for the equation: Y = -0.59X + 7.1 where Y is ammonia concentration in m.equiv./1. and X is pH of the specimen at 25° C.

We conclude that several buffer systems may be at work in eccrine sweat depending on the acidity. When the sweat is acid the ammonia-ammonium system pre-Phosphate is absent. When sweat is dominates. alkaline the carbonic acid-bicarbonate system is prominent. Amino-acids may affect the acid-base balance at any acidity.

Stimulation of Egg Laying: Possible Neuroendocrine Function of Bag Cells of Abdominal Ganglion of Aplysia californica

Two groups of identified cells in the abdominal ganglion of Aplysia californica have been classified as neurosecretory on the basis of several morphological features1,2. These are the two clusters of bag cells and the white cells R3-R14 (Fig. 1). To investigate the possible neurosecretory function of this ganglion I homogenized four ganglia, and injected the material into the haemocoel of a small animal. Twelve hours later I found a string of gelatinous material resembling the eggs which are occasionally laid by larger animals. This suggested that the ganglion contains a substance which stimulates egg laying. examine this possibility further four ganglia from large animals (500-700 g) were homogenized in 0.25 ml. of sea water in a small glass tissue grinder fitted with a glass pestle. The resulting suspension was injected into the haemocoel of a large animal (500 g) which had been isolated for a week, during which time it laid no eggs. Within 1.5 h of the injection the animal laid a string of eggs weighing approximately 2 g. In two other experiments, this animal again laid eggs after similar injections.

On the basis of their previously described electro-physiological properties¹⁻³, the bag cells seemed the more

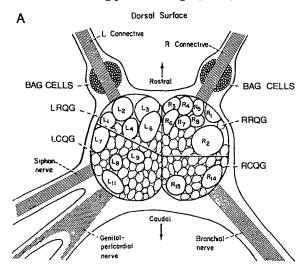

Table 1. PRESENCE OR ABSENCE OF EGG LAYING FOLLOWING INJECTION OF BAG CELL EXTRACT AND CONTROL EXTRACT

Control extract contained abdominal ganglion with the bag cells removed.

likely of the two neurosecretory clusters to be responsible for egg laying. The white cells are tonically active, and received only a very weak synaptic input. On the other hand, the bag cells are usually silent, but can be set into prolonged synchronous activity after a train of strong stimuli to the connective.

To test the hypothesis that the bag cells contained a substance responsible for egg laying, I injected animals with a preparation made from bag cells that had been removed from the rest of the ganglion (bag cell extract). Control animals were injected with a preparation made from the remaining parts of the ganglion (control extract).

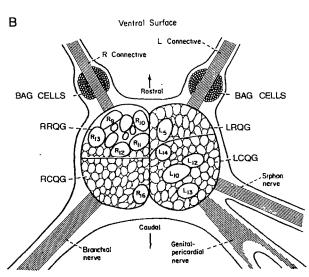

Fig. 1. Schematic representation of the abdominal ganglion of Aplysia californica showing the position of the two neurosecretory clusters: the bag cells and the white cells, R3-R14.

Bag cell extracts (Table 1) were injected into four animals and all of these laid eggs within 1 h. Two of the animals were injected with bag cell extract a second time, I or 2 days after the first injection, and they again laid eggs. Injections of control extract in these two animals and in two other animals did not induce egg laying (Table 1).

These results support the hypothesis that the bag cells. a distinct neurosecretory cluster, secrete a substance that stimulates egg laying in Aplysia.

Inhibition of Strontium and Calcium Uptake by Rat Duodenal Slices: Comparison of Polyuronides and Related Substances

It has been established that intestinal absorption o' strontium is inhibited by sodium alginate taken orally. both in the rati-3 and in man4,5, while calcium absorption is not significantly reduced. Alginic acid is a polyuronide composed of L-guluronic and D-mannuronic acid residues. both acids can occur in the same uronide chain. Polygalacturonic acid was also found to inhibit the absorption of strontium more than that of calcium, when given to rats by stomach tubes. The effect of polyuronides other than alginate and polygalacturonate on the intestinal absorption of strontium has not been ascertained.

In this study, the uptake of strontium-85 and calcium-45 by slices of rat duodenum incubated in vitro was measured in the presence of polyuronides and related substances. The method, based on that of Schachter et al... has been described elsewhere 10. Six duodenal slices from 6-8 week old male rats were incubated for 1 h at 37° C in 10 ml. of medium, the composition/ml. of which was 118 umoles of NaCl, 4·8 μmoles of KCl, 25 μmoles of NaHCO₃. 27·8 μmoles of glucose, 0·025 μmoles of CaCl₂, 0·025 μmoles of SrCl2, calcium-45 and strontium-85 as tracers, and 500 µg of test substance. At the end of the incubation the slices were assayed for calcium-45 and strontium-85. This method provided a convenient means of comparing several substances, and has been shown to give results in good qualitative agreement with absorption experiments in vivo10.

The materials investigated included sodium alginate (Manucol SS/LD/1, Alginate Industries Ltd.) containing 69 per cent guluronic acid, polygalacturonic acid (Koch-Light) and pectin (BDH). These were compared with derivatives of cellulose and amylose obtained by oxidation Two commercial oxycelluloses with nitrogen dioxide. were tested: 'Oxycel' (Parke-Davis) and 'Surgicel' (Ethicon). Oxycelluloses so formed contain high proportions of uronic acid groups but also some reducing groups indicated by high copper numbers¹¹. Amylose (Sigma) was oxidized at room temperature by NO₂ in CCl₁ (50:50 by volume) for periods from 21 to 213 h¹²; five preparations were tested. All the polyuronides were added to the incubation medium as sodium salts. The carboxyl contents of oxidized cellulose and amylose were estimated

according to Lüdtke¹³, and copper numbers were determined by Braidy's method14.

The results are given in Table 1. Alginate was included in each experiment for comparison, and in each case inhibited the uptake of strontium more than that of calcium. In contrast, strontium uptake was not inhibited more than calcium uptake by the addition of either polygalacturonic acid or pectin. Of the two oxycelluloses tested, 'Oxycel' did not inhibit the uptake of either cation, whereas uptake of both calcium and strontium was reduced by 7 per cent in the presence of 'Surgicel'. These products contained approximately the same proportion of carboxyl groups, but 'Oxycel' had a higher copper number. The oxidized amyloses had higher carboxyl contents and copper numbers than either

 β -1,4-poly-D-mannuronic acid

 β -1,4-poly-D-galacturonic acid

 β -1,4-poly-D-glucuronic acid

Fig. 1. Structures of polyuronides referred to in the text.

oxycellulose; all of them inhibited strontium and calcium uptake to a limited extent, but did not reduce the uptake of strontium more than that of calcium.

The selective inhibition of strontium uptake by sodium alginate confirms previous work¹⁰, in which it was also shown that the inhibition of strontium uptake relative to calcium was increased when the guluronic acid content of the alginate was increased. From this and the Sr/Ca selectivity coefficients for various alginates given by Haug and Smidsrød¹⁵, it can be concluded that the selective inhibition of strontium uptake by alginates is produced by the guluronic acid residues they contain. Polygalacturonate reduced the uptake of calcium and strontium about equally, in contrast with the greater inhibition of strontium absorption observed in vivo8. Of all the substances investigated, only sodium alginate inhibited strontium more than calcium uptake in vitro. The explanation for this is presumed to lie in the configurations of the various polyuronides (Fig. 1). It is not known whether the L-guluronic acid residues of alginate are α-linked or βlinked; the D-mannuronic acid residues are \$-1,4-linked (ref. 16), and so are the p-galacturonic acid units of polygalacturonic acid and pectin. 'Oxycel' and 'Surgicel' can be regarded as β -1,4-polyglucuronic acid, in which are also some reducing groups and in which not all the C₆ groups are oxidized to carboxyl: the theoretical carboxyl content of a polyuronic acid is 568 m.equiv./100 g. The various oxidized amyloses were presumed to be α-1,4polyglucuronic acid, but containing additional carboxyl groups other than those at C6, as well as some reducing groups.

I suggest that the ability of sodium alginate to inhibit uptake of strontium more than that of calcium arises from the particular disposition of functional groups, such as carboxyl, in polyguluronic acid; that this configuration favours the preferential binding of strontium ions; and that it is not reproduced in the other polyuronides considered in this study.

I thank Drs G. E. Harrison and E. R. Humphreys for helpful discussion and Mrs C. Stirling for technical assistance.

Sperm Maturation in Rabbit Epididymis

In mammals, spermatozoa mature while passing through the epididymis. Whether or not the factors governing the maturation process are intrinsic to the spermatozoa1 or whether they reside in the epididymal secretions is not

In the rabbit, there are virtually no fertile spermatozoa in the caput or proximal corpus epididymidis, and fertilizing ability is suddenly acquired when the spermatozoa pass through the distal region of the corpus epididymidis3-6. This, and the fact that, in the rabbit, the normal time which spermatozoa spend in each epididymal segment is known, makes this species especially suitable for investigating sperm maturation.

To determine whether the development of fertilizing ability depends on passage through the distal region of the corpus epididymidis, spermatozoa were retained for different times by double ligature in the proximal caput, distal caput, or the proximal region of the corpus epididymidis. Testes were reached by means of either an abdominal or a scrotal incision, and after the operation they were gently pulled back into the scrotum by a vacuum cleaner applied to the exterior of the scrotum. Ligatures were applied so as to avoid damage to the vascular system of the epididymis. When the proximal and distal caput were ligatured, the whole caput was detached from the testis, the fat was trimmed around the flexure region and one ligature was made on the flexure, and another at the junction of the caput and the corpus. At autopsy, testes and epididymides were removed. The ligatured epididymal regions from both sides were cut up in 1 ml. of 9 per cent sodium chloride. Sperm suspensions were injected through the uterine wall of both uteri of a doe injected 75 min before with 50 IU of human chorionic gonadotrophin (HCG). In each case another doe, serving as a control, was injected with the same number of spermatozoa from the cauda epididymidis. Females were killed 25 h after injection of HCG. The oviducts were flushed and the eggs recovered were examined with the ordinary and phase contrast microscope for evidence of fertilization. The criterion for fertilization was the presence of both pronuclei or of cleavage. After fertilization had been demonstrated, the coverslip was pressed down to squash the ova, and spermatozoa in each ovum were counted. When spermatozoa were trapped in a layer of mucin, their number, determined before squashing, was subtracted from the total.

In this way, it has been possible to establish the following. (a) Spermatozoa from the caput and the proximal corpus epididymidis have almost no fertilizing ability (Tables 1 and 2). Below the middle corpus spermatozoa are able to fertilize; 57 per cent of 142 ova exposed to spermatozoa from the distal corpus were fertilized. (b) When retained in the proximal corpus epididymidis for 12 h (time usually required for passage from the proximal to the distal corpus region, a small fraction of the sperm population becomes fertile: 95 per cent of the ova fertilized by these spermatozoa were recovered from does inseminated with more than 9×10^6 spermatozoa (Table 1). After 24 or 72 h in the proximal corpus, more spermatozoa are fertile, for in does inseminated with only $2 \times 10^{\circ}$ spermatozoa, all ova were fertilized. The sperm population as a whole, however, is not yet fully mature, for four out of five does inseminated with 0.5×10^6 spermatozoa kept for 24 h in the proximal corpus did not become pregnant, whereas all the does inseminated with the same small number of spermatozoa from the distal cauda did become pregnant. (c) When spermatozoa were retained by ligature in the distal region of the caput epididymidis for 1 day, 3 days (normal transit time for spermatozoa from this region to reach the distal corpus region7), 8 days or 12 days, very few spermatozoa become fertile. The only fertilization was in a doe inseminated with 40×10^6 spermatozoa. (d) Spermatozoa never become fertile in the proximal caput, even if kept there for a week, although this represents approximately the time usually needed for the spermatozoa to pass through the entire epididymal duct. (e) When testes are accidentally retained in the abdominal cavity, spermatozoa from the distal cauda epididymidis lose their fertilizing ability.

These results indicate that sperm maturation is complex. Only part of the spermatozoa in the lower corpus epididymidis are fertile, for only 57 per cent of eggs are When retained artificially in the proximal corpus region, spermatozoa can mature, although they need a longer time. Most spermatozoa from the proximal and distal caput region cannot so do. It is realized that ligature is a rather unphysiological procedure and that the secretory function of the ligatured portion of the epididymis may thereby be impaired. This does not prevent spermatozoa from the ligatured proximal corpus from becoming fertile, nor does it prevent the spermatozon from the proximal and distal caput region from developing their capacity for motility. After ligature for 8 or 12 days, spermatozoa are much more motile than usual in the epididymis. The ductuli efferentes were severed, and so most of the testes were swollen and showed patches of white seminiferous tubules full of sperm. When released in saline, these spermatozoa were motile, which is unusual for rabbit testicular spermatozoa. This confirms Young's observation1, in similar circumstances, in the guinea-pig testis. He also observed that, after isolation of the whole epididymis for 20-25 days, 44-49 per cent of the females inseminated with spermatozoa from the proximal cauda region became pregnant, whereas 33 per cent became pregnant when inseminated with proximal cauda spermatozoa from unligatured animals. Young concluded that sperm maturation is a process inherent to the spermatozoa, which begins before they leave the testis and continues after they have been carried into the epididymis but independently of any specific action of its secretion1. In the light of our results, it seems that spermatozoa need

BIOCHEMISTRY

Microsomal Protein Synthesis in the Isolated Perfused Liver during Actinomycin Blockage of RNA Synthesis

In mammalian tissues the mRNA template for protein synthesis has been found to be fairly stable in contrast to that in the microbes¹⁻³. An average half life of 2 h was demonstrated for the liver mRNA in steady state conditions4. Study of the cessation of protein synthesis after treatment with actinomycin, however, showed variable results. Even a very large dose of actinomycin could not affect the protein synthesis of the liver slices in contrast to that of the cell free system. In some cases, the in vitro microsomal protein synthesis was also unaltered6 although the actinomycin gradually decreased the in vivo protein synthesis7. A correlation has been demonstrated between the decay of mRNA and the cessation of the in vitro protein synthesis while RNA synthesis was blocked by actinomycin showing 8-12 h (ref. 8) and 1 h (ref. 9) to be an average half life for the liver messenger. Our own work was stimulated by conflicting reports of the effect of actinomycin on protein synthesis in the liver. We have measured the protein synthesis and changes in the messenger receptor sites in a cell free system obtained from isolated perfused liver to which actinomycin had been added.

Livers from female *CFE* pithed rats (200 g) were perfused through the portal vein^{10,11} and also through the hepatic artery. The perfusion fluid in most experiments was defibrinated whole rat blood, dialysed for 24 h at 4° C against Krebs solution containing an amino-acid mixture of the composition of normal rat blood or against washed red blood cells in Krebs solution containing 2.5 g/100 ml. of bovine albumin. An amino-acid mixture (50 mg/ 100 ml.) and glucose (50 mg) were infused during the experiment. The portal oxygen tension, the pressure and rate of flow of blood and the surface temperature of the liver were continuously recorded. The amount of haemoglobin, the haemolysis, the packed cell volume and the concentration of glucose and urea of the perfusion fluid were regularly examined. At the termination of the perfusions the concentration of different microsomal enzymes. the lysosomal activity and the morphology of the liver were carefully measured. No significant difference from the control livers was seen.

Both the control and the treated livers perfused simultaneously with the same fluid and in the same conditions

were homogenized in a medium of 0.15 molar sucrose, 0.025 molar potassium chloride, 0.01 molar magnesium chloride and 0.035 molar tris buffer, pH 7.8. Microsomal pellets were obtained by centrifuging the 15,000g postmitochondrial supernatant at 105,000g for 1 h. washed pellets of both the control and treated livers containing equal amounts of microsomal proteins were incubated for 5-30 min at 37° C in conditions such that protein synthesis takes place^{12,13} with ¹⁴C-phenylalanine (U) or a mixture of ¹⁴C-amino-acids from chlorella hydrolysate in the presence of "pH 5·0 enzyme" fractions obtained from the control animals unless otherwise stated. In some experiments, an increased amount of polyU was added to the reaction mixture and the components were adjusted for the optimal attachment of the ribosomes to the increased amount of polyU (unpublished work of The reaction was stopped with Nievel and Golberg). 10 per cent trichloroacetic acid containing cold amino-acids and the protein was purified by carefully extracting the acid soluble, lipid and nucleic acid fractions. The dry precipitates were dissolved in NCS solubilizer and transferred to vials, mixed with a toluene containing scintillator and counted in a Nuclear Chicago model 720 liquid scintillation spectrometer, using the channel ratio method for the quenching correction.

An increasing amount of actinomycin D, up to 1.5 mg added to the perfusion medium for 5 h, produced only a variable decrease in the protein synthesis (Table 1). The effect was seen only in the microsomes and the results were not affected whether the "pH 5.0 enzymes" were derived from the control or treated liver. No correlation was observed between the effect on the microsomes and the period of exposure of the liver to perfusion with actinomycin. The nuclear RNA synthesis of the isolated liver is greatly reduced by doses much smaller than those which we used14. It is therefore possible that the observed reduction in the rate of incorporation was a result of non-The reduction in the incorporation, specific effects. however, was accompanied by different rates of polyU directed phenylalanine incorporation (Table 2). longer the liver was exposed to perfusion with actinomycin, the faster was polyphenylalanine formed. polyU dependent increment of the treated liver was greater than that of the control perfused for from 3.5 to 6.5 h.

^{*} Percentage of the control endogenous protein synthesis.
† PolyU dependent increment: percentage of the corresponding endogenous incorporation.
† Experiments with the perfusion of washed red blood cells.

These changes were not affected if whole blood or a semisynthetic medium with washed red blood cells was perfused. Similar results were obtained in vivo after up to 2 days of pretreatment with a corresponding amount of actinomycin (unpublished work of Nievel and Golberg). Assuming that there is a common receptor site for the mRNA and for the external coding agents, the polyU dependent increment reflects loss of endogenous mRNA bound to the ribosomes¹⁵. No concomitant decrease in the ability of the isolated microsomes to synthesize protein was observed. Similar results were obtained for the in vitro protein synthesis in different experimental conditions.

The different reactions of the treated and control microsomes to stimulation by polyU, in comparison with unstimulated endogenous incorporation on the one hand and the absence of any effect of actinomycin on the microsomes on the other, point to the complexity of the interpretation of the messenger decay obtained either from the gradually decreasing protein synthesis or from the increased stimulation by polyU. If, however, the template for protein synthesis in the liver is very stable, the increase in the messenger receptor sites reflected by the increased incorporation dependent on polyU possibly does not demonstrate the decay of that messenger coding for most of the protein synthesis of the perfused liver.

In vitro "Lipid" Metabolism in the **Developing Human Foetus**

Ir can be concluded from animal data that the human foetus synthesizes lipids, chiefly from carbohydrates1-3. We have measured the synthesis of fatty acids and sterols from acetate and citrate in human foetal tissue taken at various periods of gestation. The total lipid content of the organs and the ability of the 8 week placenta to take up palmitate and incorporate it into lipids was also determined.

Tissues were obtained from foetuses after therapeutic interruption of gestation at 8, 16, 23, 24, 26 and 28 weeks. The mammary glands of two postpartum rats 10 days old were used as controls of enzyme activity. The various tissues were washed in cold isotonic saline and homogenized in 0.25 molar sucrose. The protein contents of the microsomal and supernatant fluid fractions of the homogenates were measured after high speed centrifuga-Acetate-1-14C (10 μmoles) or citrate-1-5-14C

 $(3 \times 10^6$ d.p.m. and $2 \cdot 0 \times 10^5$ d.p.m., respectively, New England Nuclear, Inc.) was added to 1.0 ml. of medium in each incubation vessel⁵. The optimal reaction was started by the addition of supernatant fraction (5 mg of protein/1.0 ml.) and microsomes (1.25 mg of protein in 0.2 ml. of 0.25 molar sucrose). The incubation vessels were maintained at 38° C for 45 min. After incubation, lipids were extracted, dried under a vacuum and dissolved in chloroform. Samples of 0.5-0.8 ml. of lipid extract were mixed with 0.5 mg of a mixture of standard lipids (Applied Physiology Laboratory). The extracts were fractionated by thin-layer chromatography?. Phospho-The extracts were lipids, free fatty acids and triglycerides were scraped from the plates, pooled and saponified in the presence of 4 per cent potassium hydroxide in 95 per cent ethanol at 100° C for 1 h. After acidification and extraction with hexane, the fatty acid residue was dissolved and counted in a scintillation counter. Sterol fractions were scraped directly into the scintillation vial containing a mixture of toluene with 4 per cent 'Cab-o-Sil' and 4 g/l. of BBOT (Packard Inst.) and were counted in the same way. Duplicate determinations of total lipid and protein content were made of two tissue samples for each period of gestation4,8. The ability of placental tissue to incorporate fatty acids was tested by incubating slices from two 8 week human placentas8 in a medium containing free fatty acids. Disappearance of these acids from the medium and incorporation of palmitate-I-14C into tissue triglycerides and phospholipids were determined7,8.

The data indicate that until the twenty-eighth week of gestation the human foetus is unable to form measurable amounts of fatty acids from citrate or acetate (Table 1). At 28 weeks, the foetal liver is as active as the adipose tissue of the rat mammary gland. The foetus then becomes active in fatty acid production from carbohydrate metabolites. Because citrate-1-5-14C is a better fatty acid precursor than acetate-1-11C, the foetal liver probably contains the citrate cleavage enzymes which can be demonstrated in rat mammary gland. The concentrations of liver and brain lipids increase 2.5 and 3 times, respectively, between the eighth and the sixteenth weeks of gestation but tend to remain constant thereafter except for samples of brain tissue which have a high value of 72 mg/g at 28 weeks. Placental lipids tend to decrease after the twenty-sixth week of gestation. Lung lipids show little change with age (Table 2). Because all foctal tissuecontain measurable amounts of lipids at each period of gestation studied, the foetus must obtain the necessary precursors from the placenta and/or maternal blood. Placental slices utilized 1.05 pequiv. of free fatty acids/g when incubated with 1.65 µequiv./ml. of fatty acid mixture. When 3.30 µequiv./ml. of fatty acid mixture was added, I g of placental slices utilized 2.45 µequiv. of free fatty acids. Placental slices took up 14.6 and 10.1 per cent labelled palmitate/g with two different levels of free fatty acids. Equal percentages (2.3 per cent and 2.4 per cent) of labelled palmitate were incorporated into placental

Control	1.9	1.5	121.3	23-2	

The results are the average of two experiments carried out in duplicate and are expressed in $m\mu m$ of substrate converted to fatty acids or sterolsing

Control: 10 day post partum rat mammary gland.

Table 2. LIPID CONTENT (mg/g) PROTEIN OF FOETAL TISSUES

Weeks of gestation	Liver	Brain	Lung	Placenta
8	80	10	_	300
16	200	30	_	260
23	220	_	190	270
26	250	34	200	230
28	250	72	160	170

phospholipids and triglycerides. Although the human placenta cannot significantly synthesize lipids from acetate or citrate, free fatty acids can be transferred into the 8 week placenta, where they can be converted into placental lipids in vitro. Circulating maternal fatty acids could thus be precursors of foetal lipids until the twenty-eighth week of gestation. This infers that foetal lipids are not synthesized de novo from carbohydrates before the twenty-eighth week of gestation. Hirsch's data demonstrate that dissimilarities in fatty acid composition can be detected between mother and foetus?. Partial or total de novo synthesis from carbohydrate is possible in term foetal tissue, and our results show that this takes place as early as the twenty-eighth week of gestation. Additional evidence for the possible maternal origin of fatty acids in young foetuses is that the human placenta transfers fatty acids in vitro (our data) and in vivo to the foetus10.

Lipoprotein lipase is also present in the syncytium¹¹. In contrast, Villee has published data which show a small conversion of acetate 2-¹⁴C to lipids by foetal liver and placental slices as early as the twentieth week of gestation3. We suggest that most of the measured radioactivity could be in the non-fatty acid fraction of the phospholipids and triglycerides.

The synthesis of fatty acids and sterols from acetate-1-14C or citrate-1-5-14C by brain tissue starts as early as the sixteenth week of gestation. This may well be related to the development of independent brain myelinization.

Inhibition by Cortisol of Deiodination of Thyroxine by Rat Liver in vitro

GLUCOCORTICOIDS have been shown to flatten the slope of peripheral disappearance of 121 I-thyroxine in man1 and decrease its hepatic content in man² and rat³. Galton and Ingbar4 have shown that deiodination of thyroxine by rat liver is mediated by two components, one of which is heat resistant and lost by leaching of liver slices in buffer and another which is heat labile and possibly an

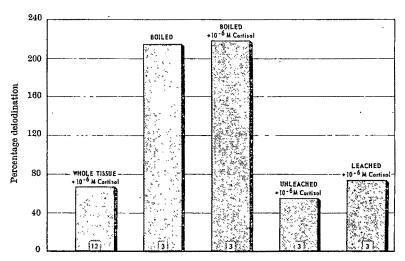

Fig. 1. Shows mean values for percentage deiodination. The number of experiments is indicated at the bottom of each column.

This latter component is probably similar to enzyme. the heat labile, microsomal system for degrading thyroxine

We used male Sprague-Dawley rats (200 g), and pieces of liver of known weight were homogenized at 4° nine volumes of Krebs Ringer phosphate buffer pH 7.4. In leaching experiments, weighed liver slices were kept in 50 ml. of this buffer for 30 min and then homogenized in fresh buffer. In some experiments, liver homogenates were boiled for 15 min, cooled and rehomogenized before use. All incubation vessels contained I ml. of homogenate and 1×10^{-7} to 4×10^{-7} molar ¹³¹I-thyroxine in 1 per cent human serum albumin. Cortisol was added in the final concentration of 10-6 molar. In control vessels the volume was made up with buffer. After incubation for 1 h at 37° C in a metabolic shaker, 1 ml. of plasma was added to each vessel to stop further reaction. Chromatographic quantification of deiodination was achieved by the method of Galton and Ingbar⁶. Both original material and iodide were combined for calculating the deiodination. Deiodination of ¹³¹I-thyroxine by the rat liver microsomal system was investigated by the method of Wynn et al.5. All results are expressed in terms of deiodination by the control liver homogenate or microsomal system taken as 100 per cent.

Figure 1 shows the inhibition of deiodination by whole liver homogenates by 10-8 molar cortisol. In paired experiments, leached homogenized slices showed only slightly less inhibition than unleached controls. Cortisol, however, had no effect on deiodination by boiled homogenates (increase in deiodination after boiling has been noted previously4). Cortisol (10-6 molar) had no effect on the percentage of iodide in the buffer or Krebs Ringer phosphate buffer in which liver slices had been leached. Cortisol produced inhibition of deiodination by the rat liver microsomal system which requires 7×10^{-4} molar ferrous sulphate for its optimal activity. Percentage deiodination in the presence of varying concentrations of cortisol was as shown in Table 1 (average of duplicate or more observations in six experiments).

Our results therefore indicate that the inhibitory effect of cortisol is probably on the enzymatic deiodination of thyroxine. The decrease in deiodination of thyroxine would contribute to the flattening of peripheral degrada-

Table 1. PERGENTAGE DESORDINATION IN THE PRESENCE OF CORTISOL

Cortisol	Percentage deiodination
10 ⁻⁴ molar	76-8
10 ⁻⁵ molar	74-5

Competitive Inhibition of Histochemical Substrates for Glycosidases

HISTOCHEMICAL reactions are dependent on enzyme specificity. The reaction should be enhanced by conditions that are optimal for the enzyme and should be diminished in the presence of inhibitors. Inhibition of the substrate reaction may be effected either by enzyme inactivation or by competition with analogous compounds. methods have been used to define the specificity of numerous in vivo and in vitro biochemical systems.

Halogen-substituted indoxyl substrates have been synthesized recently for $\beta\text{-D-galactosidase}^1$, $\beta\text{-D-glucosidase}^2$, $\beta\text{-D-glucuronidase}^3$ and $\beta\text{-D-fucosidase}^4$, and enzyme specificity has been demonstrated for each. The substrates contain an identical indolyl moiety (5-bromo-4chlorindol-3-yl) and glycosides which differ from each other only in the configuration or substitution of C4 or C8 (Fig. 1). We observed the comparative effect of analogue inhibitors on the reactions of these structurally similar

Specimens of jejunum were obtained from freshly killed, adult Sprague Dawley rats, frozen in a dry ice and acetone bath and sectioned in a cryostat at -15° C. The sections were incubated for 3 h at 37° C in a solution of the substrate and inhibitor. The pH range and the

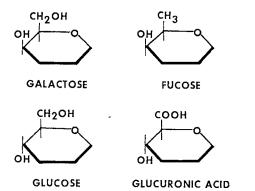

Fig. 1. Comparison of glycon moleties illustrating the structural similarity of the indoxyl substrates. In each case the compound is a β -isomer and the glycoside is in the D-configuration.

optimum pH for reactions in the jejunum were determined for each substrate. The substrate concentration was adjusted so that reactions of similar intensity were obtained for each by the end of 3 h. Sections in each experiment were prepared from a single block of tissue and were mounted at the tip of coverslips in order to conserve substrate (final incubation volume was 1 ml.). To each substrate solution, inhibitors were added so that the final concentration was 0.01 per cent to 2 per cent. After incubation, the sections were dehydrated, cleared and mounted in balsam. Inhibition was graded (0 to ++++) by the degree of diminished staining and the inhibitor concentration which was required for this effect. The staining reaction occurred over a broad range of pH values. The pH optima were: galactosidase, 5.4; fucosidase, 6.2; glucuronidase, 4.8; and glucosidase,

In general, inhibition of the reaction was most marked when both the substrate and inhibitor were derived from the same sugar. Results for the four substrates are listed in Table 1. A variable degree of inhibition resulted from addition of the sugar in the substrate to the incubating solution. Staining was diminished in the glucuronidase reaction by the presence of 0.1 per cent glucuronic acid (+++). In contrast, 2 per cent glucose had no effect on the glucosidase reaction. Aldonolactones were the strongest inhibitors, but overlapping occurred between galactosidase and fucosidase, and between glucosidase and fucosidase. Glycoside derivatives showed the specificity of carboxyl group location. Gluconic acid (C1 carboxyglucose) inhibited glucosidase activity, but had no effect on glucuronidase activity. Saccharic, galacturonic and glucuronic acid (C, carboxyl groups) all inhibited the glucuronidase reaction.

Disaccharides were weak inhibitors. Lactose (glucosido- β -galactose) was a consistent inhibitor of galactosidase only at a concentration of 2 per cent. Cellobiose (4glucosido-β-glucose) had no effect on glucosidase but weakly inhibited the fucosidase reaction. In addition to the compounds listed in Table 1, no inhibition was noted with the following commercially available sugars and sugar derivatives: L-fucose, 2-deoxyglucose, mannose, rhamnose (6-deoxymannose), sorbose, ribose, L-arabinose, lyxose, fructose, inulin, stachyose (Lupeose), sucrose (4-fructosido- $\alpha\text{-glucose}),$ maltose (4 glucosido- $\alpha\text{-glucose}),$ trehalose (1-glucosido- $\alpha\text{-glucose}),$ raffinose (melitriose), ducitol (galactitol), sorbitol (glucitol), inositol, adonitol, N-acetylglucosamine and phospho-glucuronic acid. The substrate hydrolysis was identical in these four indolyl glycosidase methods, and the rate and intensity of the staining reactions were similar. The overlapping inhibition between galactosidase and fucosidase activities in this study has

Table 1. INHIBITION OF INTESTINAL GLYCOSIDASES

++++, Complete inhibition, 0·1 per cent; diminished staining, 0·01 per cent. cent. These sugars and sugar derivatives were all in the D form.

been noted previously in biochemical assays. Similarly the inhibition of glucosidase activity by xylose is probably the result of similarities between glucosidase and xylosidase and/or the similar configuration of glucose and xylose6.

These data confirm enzyme specificity for glycoside configuration and linkage7. Neither L-fucose nor αlinked glycosides had the inhibitory effect of D-fucose and β-linked glycosides. Carboxyl substituents seemed to be more important than either other end groups or the configuration of the pyranoside ring. Rhamnose (6deoxymannose) did not inhibit fucosidase, but all compounds with C₆ carboxyl groups were strong inhibitors of glucuronidase. In contrast, glucose and galactose derivatives did not necessarily inhibit glucosidase and galactosidase. There is no obvious explanation for the absence of glucosidase inhibition by glucose. The reason for the weak inhibition of fucosidase activity by gluconolactone and cellobiose or the similar effect of melibiose (6-galactosido-α-glucose) on glucosidase is also unknown.

Dannenberg and co-workers8 have used histochemical methods to study the conditions of activation and inhibition of several hydrolytic enzymes in macrophages (unpublished data) and Fishman et al.9 have studied the inhibition of glucuronidase. These data confirm their findings with compounds analogous to the galactoside and glucuronide. These studies demonstrate that analogue and end-product inhibition are useful techniques for defining the specificity of histochemical methods for enzyme detection. I thank Arthur M. Dannenberg, jun., and Bjarne Pearson for their advice and assistance.

Imidazole and Sequestration of Calcium Ions by Sarcoplasmic Reticulum

SARCOTUBULAR fragments prepared from homogenates of skeletal muscle are able to sequester vigorously calcium ions if ATP is available, and they show the activity of Mg-ATPase and Ca-ATPase which are thought to serve in the energy requiring sequestration of calcium ions. Although these functions have been the subject of much experimentation, little is known about their molecular bases. The uptake and release of calcium ions by the sarcotubular system are believed to be an integral part of excitation-contraction coupling and relaxation of muscle, and so it is important to understand the molecular mechanisms which underlie these processes. Hasselbach and Seraydarian¹ have reported that certain sulphydryl groups of the sarcotubular membranes play an important part in both the uptake of calcium ions and the related ATPase activities. Experiments carried out in our laboratory, however, indicate that a functional group other than the sulphydryl is also involved in these activities.

A purified sarcotubular fraction was prepared from rat skeletal muscle by a modification of the method of Seraydarian and Mommaerts² and this fraction had two to three times as much Mg-ATPase and calcium ion sequestering activity as the unpurified microsomes.

The effect of ageing the purified sarcotubular fragments on their calcium ion sequestering and Mg-ATPase activities was examined by suspending them in 0.25 molar sucrose (about 0.7 mg of sarcotubular protein/ml. of suspension). This suspension was stored at 2° C and samples were taken periodically to follow the course of ageing on calcium ion sequestration and Mg-ATPase activities. Various chemical agents were added to test their ability to modify the effect of ageing; unless otherwise stated, these agents were added at a concentration of 5 mmolar at zero time.

Mg-ATPase was assayed as follows: a 2 ml. system containing 20 mmolar tris-hydrochloric acid (pH 7·2), 3 mmolar magnesium chloride, 3 mmolar ATP and 50 μg of sarcotubular protein was incubated for 20 min at 37° C; the reaction was stopped by adding 0.2 ml. of 50 per cent trichloroacetic acid. The inorganic phosphate liberated was measured colorimetrically by the method of Fiske and Subarrow³

The uptake of calcium ions by the sarcotubular fragments was measured in the incubation system of Carsten and Mommaerts⁴. Samples were removed from the system at various intervals, and the amount of calcium-45 bound by the sarcotubular fragments was measured by the 'Millipore' filtration method of Martonosi and Ferretos.

After solubilizing the protein of the sarcotubular fragments with 0.16 per cent deoxycholate and heating on a steam bath, the protein concentration was measured colorimetrically by the method of Lowry et al.6.

The effect of ageing on the capacity to sequester calcium ions is shown in Fig. 1. The sarcotubular fragments lose their capacity to bind calcium ions when they are stored in 0-25 molar sucrose, but not when stored at higher sucrose concentrations (for example, 0.5 molar and 1 molar). Compounds containing pyrophosphate, such as ATP, ADP and inorganic pyrophosphate, prevent loss of the ability to take up calcium ions during ageing, while cyclic AMP and creatine phosphate are far less effective. Albumin (1 per cent) also prevents loss of sarcotubular calcium ion sequestering activity during ageing. Albumin contains sulphydryl groups and so we felt that these functional groups might be responsible for its protective effect, but none of the tested sulphydryl reagents (Cleland's reagent, glutathione, cysteine) prevented the diminution of activity during ageing. EDTA (2.5 x 10-5 molar) also failed to protect. Imidazole compounds markedly protect

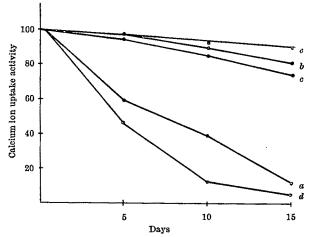

Fig. 1. Effect of various reagents on ageing of calcium sequestration occurring in fragments of sarcotubular membrane. Concentration of sucrose (a), 0-25 molar; of ATP (b), histidine (c) and glutathione (d), 5 mmolar; of albumin (e), 1 per cent. Temperature for storage was 2° C. Concentration of microsomes, 0-7 mg of protein/ml. Activity is expressed in relation to zero time value which is arbitrarily set at 100.

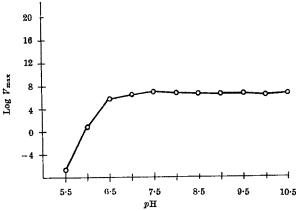

Fig. 2. 11 cct of pH on the log V_{max} of Mg-ATPase. V_{max} was obtained from the cuble reciprocal plot of ATPase activity against ATP concentration at different pHs. V_{max} was determined in optimal conditions with regard to the ratio of [Mg++] to [ATP] and total [ATP] at each pH

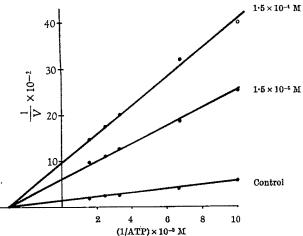

Fig. 3. Effect of photo-oxidation with rose bengal on calcium uptake by sarcotubular fragments. (The control experiment involved the same concentration of rose bengal but no illumination.)

the activity during ageing, histidine and urocanic acid being considerably more effective than imidazole and imidazole acetic acid. The amino-acids arginine, serine, cystine, methionine and tryptophan also protect the calcium ion uptake activity during ageing but are much less effective in this respect than the imidazole compounds. The activity of Mg-ATPase in the sarcotubular fragments is also lost during ageing but can be protected from this effect by the same agents which protect the calcium ion sequestration system. There is one exception: Cleland's reagent does not protect the sequestration of calcium ions but does protect the Mg-ATPase system.

These data suggested that the imidazole group plays a part in the biochemistry of the sequestration of calcium ions by sarcotubular fragments. Because the sequestration of calcium ions and the activities of ATPase are thought to be related, we investigated the molecular basis of the sarcotubular Mg-ATPase activity. In Fig. 2, the log $V_{\rm max}$ of Mg-ATPase is plotted on the y axis and the $p{\rm H}$ on the x axis. The activity of Mg-ATPase seems to be independent of $p{\rm H}$ when the $p{\rm H}$ is greater than 6.5, but when the $p{\rm H}$ is less than 6.5 the activity of Mg-ATPase declines rapidly as the $p{\rm H}$ decreases. These data imply that the Mg-ATPase involves a group with a pK near 6.5. Of the amino-acid residues in the protein of the sarcotubular membranes, the histidine residues are the ones most likely to have a pK near 6.5 (ref. 7).

Imidazole groups are photo-oxidized in the presence of methylene blue⁸ or rose bengal⁹. Sarcotubular fragments were therefore subjected to the following treatment. They

were suspended in 35 per cent sucrose solution (approximately 100-150 mg of sarcotubular protein/ml. of suspension) containing either 5×10^{-7} molar rose bengal at pH 7.4 or 5×10^{-6} molar methylene blue at pH 6.8 and were illuminated with a 100 W tungsten lamp, without shaking at 2° C. At the time intervals of Fig. 3, samples were assayed for evidence of calcium ion sequestration. In the case of both rose bengal (Fig. 3) and methylene blue (data not recorded) photo-oxidation caused a marked loss of ability to sequester calcium ions. The effect of similar treatment on Mg-ATPase activity was examined; illumination was carried out while ATPase activity was being assayed (incubation for 15 min at 37° C). Rose bengal (not shown) and methylene blue (Fig. 4) competitively inhibit the activity of Mg-ATPase. Although these photooxidation experiments are consistent with the concept that imidazole groups function in both the sequestration of calcium ions and the activity of Mg-ATPase in the sarcoplasmic reticulum they do not provide unequivocal proof. for methionine and tryptophan residues are also attacked by the photo-oxidation procedures.

The effects of sulphydryl inhibitors on the ATPase activity of the sarcoplasmic reticulum were also investigated (Fig. 5). In contrast to the effects of photo-oxidation, salyrgan functions as a non-competitive inhibitor of the ATPase as does p-chloro-mercuri-benzoate (PCMB), while N-ethylmaleimide (NEM) is an uncompetitive inhibitor of the sarcotubular Mg-ATPase.

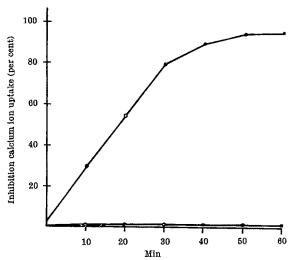

Fig. 4. Competitive inhibition of Mg-ATPase by methylene blue. Plot of reciprocal velocity 1/V (where V is μ g of inorganic phosphate formed in 20 min) against 1/[ATP] (where [ATP] is in mmolar). The control experiment involved the same concentration of methylene blue but no illumination.

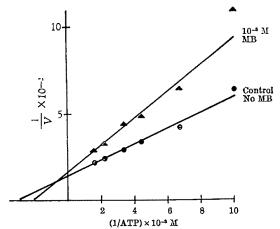

Fig. 5. Non-competitive inhibition of Mg-ATPase by salyrgan, plotted as in Fig. 4.

The photo-oxidation data are consistent with the presence of some group other than thiol (such as histidine, tryptophan or methionine) at a site concerned with the sequestration of calcium ions by sarcotubular membranes and of such a group in sarcotubular Mg-ATPase activities, these groups perhaps being involved in the binding of the relevant substrates. The pH dependence of the sarcotubular Mg-ATPase and the marked protective action of imidazole compounds against loss of Mg-ATPase activity and the ability to take up calcium ions during ageing of the sarcotubular fragments strongly suggest but do not rigorously prove that it is the imidazole group which is

Role of Intestinal Lymphatics in Copper Absorption

THE immediate appearance of copper-64 in the peripheral blood of rats, rabbits, sheep and men after oral ingestion of the isotope indicates that the upper gastrointestinal tract is an important site for the absorption of copper¹⁻³. The role, if any, of the intestinal lymphatics in the absorption mechanism is unknown and has not been reported. In order to elucidate this role, we have compared the relative proportions of absorbed copper which are transported from the intestine by portal blood and by lymph.

Three mongrel dogs, weighing 12-15 kg, were anaesthetized with intravenous pentobarbital. After laparotomy, an 'Intramedic PE 120' polyethylene catheter was passed into the portal vein through a mesenteric vein and was kept patent during the intervals between sampling by means of a slowly dripping solution of 5 per cent dextrose in normal saline containing 10 U of heparin/ml. A second catheter was inserted into the thoracic duct at its junction with the subclavian vein to collect lymph during the period of the experiment. As soon as lymph was flowing freely, 0.5 mc. of copper-64 nitrate containing 600 µg of ionic copper was administered in milk to each animal either through a peroral rubber tube into the stomach or by a duodenostomy. In one experiment, the milk mixture was placed just beyond the ligament of Treitz into a 12.5 cm loop of jejunum isolated by ligatures at both ends. The concentration of copper-64 in plasma and lymph was assayed in a Nuclear-Chicago well-type scintillation detector DS 202 (V) and a model 8725 analyser/ scaler. One millilitre of portal blood was drawn at intervals of 5-15 min for about 90 min. All the lymph flowing from the thoracic duct was collected during the same intervals. The mean concentrations of copper-64 in plasma and lymph, determined in three experiments, were plotted against time. Figure 1 shows that the copper concentration of lymph rises more slowly than that of portal blood

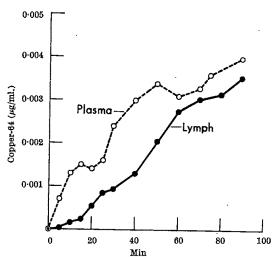

Fig. 1. Mean concentrations of copper-64 in plasma and lymph at various times following administration of copper-64 nitrate to three dogs.

and remains much lower for approximately 1 h, after which concentrations of copper in both fluids tend to become equal. Of the 600 µg of copper placed in the loop of jejunum which was tied off, 310 µg remained in the lumen and intestinal wall after 90 min. Of the 290 µg of copper absorbed, only 0·12 μg was recovered from the total of 38 ml. of lymph collected in this period. The remainder—little less than 290 µg—clearly had been absorbed through the blood which could not be collected quantitatively.

The quantitative insignificance of lymphatic absorption of copper has also been noted in a study with a man aged 28 suffering from Laënnec's cirrhosis and portal hypertension. Following therapeutic catheterization of the thoracic duct (for decompression of ascites4) and umbilical vein, the concentration of copper-64 given intragastrically in a dose of 1,000 μg of copper reached 0.005 μg in 192 ml. of lymph, collected over 110 min. The concentration of absorbed copper in lymph is lower than that in portal blood (Fig. 1) and the volume of lymph produced in a given time is considerably less than that of portal blood flow4, and so the amount of copper absorbed through the lymph is negligible compared with that transported through the blood. Albumin binds almost all copper immediately after absorption and is present in roughly equal concentrations in lymph and blood4, and is therefore unlikely to account for the difference in copper absorption observed. Amino-acids which are passed into the portal circulation⁶ also bind copper⁷. This suggests a possible role for these substances in the transport of the metal across the mucosa.

Antilipaemic Effect of Nicotinamide

THE antilipaemic effect of nicotinic acid is well known¹ and the clinical value of this compound as an agent for lowering the content of cholesterol has been demonstrated^{2,3}. Although many explanations have been offered, the mechanism by which nicotinic acid exerts its antilipaemic effect is not known. It is generally agreed, however, that the effect of decreasing cholesterol is unrelated to this compound's known vitamin role as a precursor of pyridine nucleotides, because nicotinamide, which is more readily incorporated into pyridine nucleotides, has little effect on serum cholesterol concentrations in man^{2,3}.

I have shown that nicotinamide is as effective as nicotinic acid in decreasing the concentration of cholesterol. triglycerides and free fatty acids in the serum of the rat. I have also shown that both agents are very effective in decreasing the content of serum triglycerides and free fatty acids in the dog. Animals were fasted 16 h before they were given the drug (2 mmoles/kg); blood was campled at various times. Blood lipid was assayed by standard analytical methods. In the rat, all lipid classes measured were considerably reduced by both agents (Table 1). Similarly, free fatty acids and triglycerides in the serum were reduced in the dog but in these conditions the content of cholesterol was unchanged (Table 2). The time interval between the administration of the drug and the maximal effect on the different lipids varied greatly, and so, for the purpose of this discussion, only the maximal effects and the time at which they occurred are included in Tables 1 and 2.

A maximal decrease in free fatty acids occurred much earlier than the decrease in serum triglycerides which in turn was much earlier than the decrease in serum choles-This temporal relationship has been observed before with nicotinic acid4,5. So pronounced is the effect of nicotinic acid on concentration of free fatty acids in serum that it has been suggested that the primary activity of this acid is to inhibit the release of free fatty acids from adipose tissue depots, while the effect on other blood lipid constituents is an indirect consequence of this activity4,5.

A reduction in cholesterol content caused by nicotinamide and nicotinic acid in rabbits fed cholesterol has been reported by Fontenot⁶. The reduction was paralleled by a corresponding increase in nicotinamide adenine dinucleotide (NAD) in packed erythrocytes. It was suggested that the antilipaemic action of nicotinamide is unique to the rabbit. The experiments reported here indicate that in two other species nicotinamide is as effective as nicotinic acid as an antilipaemic gent.

Ricci and Pallini7 found an increase in free nicotinic acid in the liver of rats injected with nicotinamide, thus

demonstrating the presence of a pathway for conversion of nicotinamide to nicotinic acid. This pathway may also exist in the dog and rabbit, which would be consistent with the in vitro data which indicate that the hypolipacmic effect of these substances is a consequence of the presence of free acids. The lack of antilipaemic activity of nicotinamide in man may mean that the conversion pathway does not exist. The demonstration of an antilipaemic action of nicotinamide in some species must be taken into consideration when explaining the mechanisms by which nicotinic acid and related compounds decrease concentrations of cholesterol. A vitamin effect of these substances cannot be disregarded yet.

CYTOLOGY

Structural Basis of Quantitative Variation in Nuclear DNA

RECENT surveys show that variation in the amount of nuclear DNA, quite independently of change in chromosome number, is frequently associated with the divergence and evolution of both plant and animal species 1-10. The extent of such variation is often very great, particularly among the anglosperms. One of the many problems posed by these findings is the nature of the chromosome structural changes which give rise to the DNA variation. Two proposals have been put forward. The first is a differential polynemy, that is, a difference in the lateral multiplicity of DNA strands between chromosomes of different species4,9. While this proposal has many theoretical attractions there is, to date, no direct evidence in its favour. Indeed, Callan¹¹ has adduced evidence which argues strongly against this view. The second possibility is that the nuclear DNA variation is caused by lengthwise incorporation or loss of chromosome segments such as result from duplication or deletion. Observations in Lolium, and in Chironomus, hybrids at pachytene of meiosis and in polytene nuclei, respectively, show that the chromosomes of species with different nuclear DNA contents differ in respect of segmental duplications. There are therefore good grounds for attributing at least part of the DNA variation to such duplications. The following work in Allium provides further evidence to support this view. What is more, it shows that segmental duplications can account entirely for the DNA charges observed.

The nuclear DNA content of Allium cepa is about 27 per cent greater than that of A. fistulosum (Table 1). The A. cepa chromosomes, as would be expected, are correspond-

Note the asymmetry of bivalents. b, An isolated chromosome pair with an interstitial loop (l) and terminal overlap (a) resulting from duplication (or loss) of chromosome segments. The duplicated segments comprise about 35 per cent of the total length. c, Probable position of the centromere.

ingly larger than those of A. fistulosum. It can easily be shown that structural differences which account for the chromosomal DNA variation are spread throughout all members of the chromosome complement. This follows from the fact that in the species hybrid all bivalents at first metaphase of moiosis are asymmetrical (Fig. 1a) and all univalents of a pair are unequal. Measurements of chromosome lengths in the bivalents and among univalents show that the size and hence the DNA differences between homolog ous chromosomes range from about 10 per cent to 60 per cent. If these differences are completely accounted for by segmental duplications it follows that in each pair of chromosomes at pachytene we should expect extensive loops or overlaps comprising from 10 per cent to 60 per cent of the total length. Allium pachytenes do not lend themselves readily to a complete analysis. We have, however, isolated a number of different chromosome All the isolated pairs show loops and overlaps caused by duplications. An example is shown in Fig. 1b. Moreover, the duplicated seg nents make up the expected 10 to 60 per cent of the total length—sufficient to account entirely for the DNA variation without having to invoke a differential polynemy.

APPLIED SCIENCE

Tensile Strength of Wet Granular Materials

CARR¹ has explained the decrease in the tensile strength of wet granular materials with decreasing moisture content by assuming that the decrease in the number of liquid bridges, spanning the gaps between particles, outweighs the gain in strength of the remaining bridges as their volume is reduced. We have analysed this argument for a packing of equal spheres using our results for the properties of liquid bridges between equal spheres2 and for the spatial distribution of spheres in a random pack-These have been combined with the theoretical results of Fisher4.

The attractive force caused by a liquid bridge between equal spheres shows an approximate linear decrease with sphere separation from a maximum F_{max} , near contact, to zero, at the rupture separation x_r . There is a linear relation between x_r and the bridge neck diameter at contact, so that x_r may be obtained by extrapolation, knowing the properties of the bridge at contact² (Fig. 1). Fisher4 has calculated the attractive force and neck diameter for bridges at contact (Table 1). These results make it possible to construct force against separation diagrams for bridges of different volumes. These follow an approximate law.

$$F_x = F_{\text{max}} \left(1 - \frac{x}{x_r} \right) \tag{1}$$

where F_x is the force at separation x, x being expressed in sphere diameters. For convenience, the normalizing factors used by Fisher are used where appropriate.

The results on the random packing of spheres yield an approximate equation of the form3

$$N_x = 7.6 + 14.4 x \tag{2}$$

where N_x is the average number of spheres with surface separations less than a distance x around a central or datum sphere. This approximation holds from x=0 to about x = 0.5, so that

$$\frac{\mathrm{d}N}{\mathrm{d}x} = 14.4\tag{3}$$

We make the assumptions that every gap smaller than x_r in a wet sphere packing is spanned by a bridge, and

0.599	0.725	0.316
From Fi	Extrapolated from	
		Fig. 1

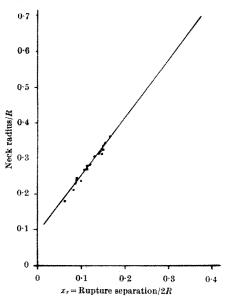

Fig. 1. Extrapolation of experimental rupture separations to larger liquid bridges.

that all bridges have equal volumes. x_r is dependent on bridge volume and hence on overall moisture content.

The total force of all the bridges acting on any sphere

total force =
$$7.6 F_{\text{max}} + \int_{0}^{x_r} \left(F - F_{\text{max}} \frac{x}{x_r} \right) 14.4 \, dx$$
 (4)

 $= F_{\max} \left(7.6 + 7.2 x_r\right)$

In tensile strength, only the force components in the direction of tension are involved. Thus the tensile strength o is equivalent to the average force exerted on a unit area of a sphere surface, therefore

$$\sigma = \frac{F_{\text{max}}}{4\pi R^2} (7.6 + 7.2 x_r) \tag{6}$$

where R is the sphere radius.

The attractive force F_{max} may be obtained from Fisher's normalized force which is equivalent to F_{max} $2\pi R\gamma$, and x_r may be obtained from Fig. 1 using Fisher's neck radius results. The moisture content of the granular material may be calculated knowing the number and volume of bridges in a packing. It is expressed as the percentage of liquid volume to solid volume in the packing. The results of these calculations are shown in Table 2. It is noticeable that σ remains roughly constant at about 3.65 γ/R dynes/cm² for a wide range of moisture content. This is about five times greater than experimental values and does not account for the apparent change in tensile strength with moisture content. This is because the decrease in the strength of the bridges with increasing moisture content is almost exactly countered by an increase in their number. Thus the original hypothesis

Table 2. Some tensile strengths of a bed of wet spheres (packing density, 0-625) calculated for different moisture contents using equation (6)

Fisher's olume of half each bridge R^3	$\frac{F_{\max}}{2\pi R \gamma}$	Extra- polated from Fig. 1	Number of bridges/ sphere = 7.5 + 14.4 xr	$\sigma \times \frac{R}{\gamma}$	Percentage of liquid by volume

0.0933	0.75	0.288	11.75	3.59	26.5

would seem to be inadequate for a quantitative explanation of experimental results. Our original assumptions might be a source of error. Presumably Carr's static method of forming wet beds of spheres would result in all the gaps below x_r being bridged, but the assumption of equal bridge volumes is more difficult to assess. If the bridges do reach a pressure equilibrium with each other. then the more highly curved bridges between contacting spheres would grow and decrease their curvature at the expense of bridges between non-contacting spheres. This should result in a decrease in tensile strength from that calculated here. Calculations using bridges of constant curvature rather than constant volume would yield quantitative information on this point.

Recording the Initiation and Development of Failure in Timber

MICROSCOPIC examinations of fractures in materials have been restricted, in the past, to the detailed study of surfaces after failure has occurred; pre-failure development within the material has remained an elusive phenomenon. Thus the changes in structure which occur during stressing have usually been deduced from information obtained from a series of blocks each being subjected to different degrees of stress. While this approach can yield valuable information on the sequential changes in the internal structure of a material before failure, it lacks continuity, because it introduces both variations between samples and a degree of subjectivity in the interpretation of the sequence from the observed stages.

The need for continuous observation during stressing was evident from recent investigations into the changes in structure which occur in timber during compression stressing and fatigue, and a visual record of these has now been achieved by sandwiching thin radial longitudinal sections of wood between a 'Perspex' sheet which has a modulus of elasticity only one-half of that of wood, parallel to the grain. The sections, cut under carefully controlled conditions to eliminate the presence of artefacts induced during microtomy^{1,2}, measured 22 mm in length by 30µ in thickness. This thickness represented a compromise between the need for thin sections for photographic examination and thicker sections to provide enough support within the wood. A 30µ section contained fibres which possessed at least one radial wall in addition to the two tangential walls, while thinner sections would have included a number of cells without radial walls, thus permitting abnormal buckling of the cell walls during compression.

The 'Perspex' supports for the compression tests were cut from 0.8 mm sheet and were 6 mm wide, and waisted in the middle to 3.2 mm. The sections were mounted between supports using a chloroform-methacrylate cement. With two-thirds of the blocks, the centre portion of the section was embedded in immersion oil while the top and bottom parts were cemented, thus allowing the centre portion of the wood section to move independently of the Perspex' (Fig. 1). In the remaining blocks, the entire section was cemented between the 'Perspex' supports, but

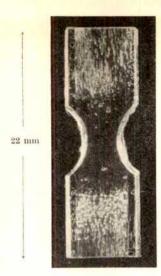

Fig. 1. Compression test piece containing a section of wood, the centre portion of which is immersed in oil while the ends are cemented.

tally between the jaws of the 'Instron', the microscope was placed at the side of the instrument and the load was transferred from the 'Instron' by fluid transfer to a compression plate attached to the mechanical stage of the microscope. This alteration provided greater flexibility in operation, particularly in microphotography, while still providing a stress-strain curve for the block.

The sequence of events occurring during compression was recorded on 16 mm ciné film and on 35 mm still film. A series of still photographs is shown in Fig. 2. Detailed results will be presented and discussed in a

later paper

This technique was designed primarily to obtain qualitative evidence to support results deduced from the examination of blocks subjected to different degrees of stress. Quantitative interpretation of the results in terms of stress is not possible, because neither the amount of interaction between the wood and the 'Perspex', nor the effective cross-section of the wood, is known. The approximate calculation of strain, however, is more feasible, because 40 per cent of the change in length of the block occurs in the waisted region. The first signs of dislocation within the fibre walls occurred at a strain of

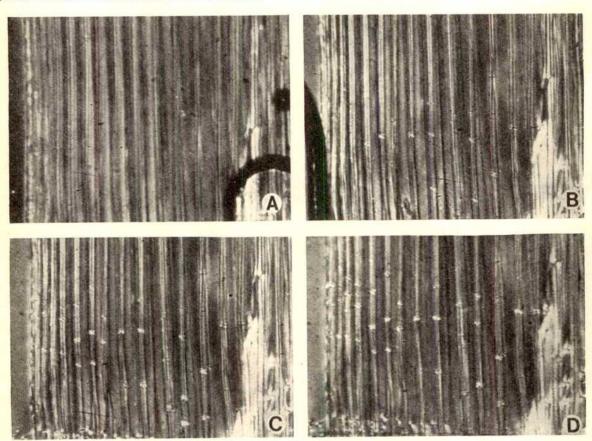

Fig. 2. Changes in the cell walls of Norway spruce timber subjected to increasing compression stress along the fibres. (A) Initial condition; (B) load 13 lb., slip planes just appearing; (C) load 21 lb., further development of these dislocations; (D) load 30 lb., preferred distribution in horizontal planes becoming apparent.

the evidence obtained from observation of these under compression indicated that at least part of the section was usually acting independently of the supports.

These blocks were compressed longitudinally in an 'Instron' testing machine, operating at a cross-head speed of 0.02 mm/min, and were viewed microscopically using a polarizing microscope and 150 W quartz iodine light source. Polarization microscopy is essential to observe the changes which occur in the orientation of the microfibrils in the cell wall. Because of difficulties in reducing the amount of vibration with the microscope slung horizon-

0.5 per cent and a stage corresponding to complete failure of the fibres occurred at a strain of 1.5 per cent.

This method is currently being used to study the changes in structure which occur during the fatigue of wood.

BOOK REVIEWS

SCHOOL PHYSICS

Physical Science

A Study of Matter and Energy. By Verne H. Booth. Second edition. Pp. xvi+742. (New York: The Macmillan Company; London: Collier-Macmillan, Ltd., 1967.) 70s.

If the Schools Council has its way with the curriculum of the sixth form and reduces the number of subjects to be studied and externally examined to two, students entering the science and technology departments of colleges and universities might well have followed a course of the type which Dr Booth has devised for "non-science majors in colleges". Such a course is very different both in degree and in kind from those now followed in sixth forms and also from those now being tested by the "A" level teams of the Nuffield Science Teaching Project.

This American course exhibits a considerable and welcome breadth, even though it is limited to a study of matter and energy. Its design is well revealed by the sequence of section headings: the solar system; force and motion; molecules and energy; the electrical nature of matter; atomic structure and chemical combination; matter and energy in the study of the Earth; the energy within nuclei. Within these sections, the treatment is largely historical. For example, the first sections trace the growth of the theories of planetary astronomy from the early days to the time of Newton, interpolating a chapter on simple mathematical ideas and symbolism (ratio, proportion, graphical representation, vectors but not the calculus). Only after the simple kinetic model of an ideal gas has been considered is any aspect of chemistry treated. This is a familiar historical unfolding of the development of the atomic hypothesis from Boyle to Mendelyeev. Subsequent chemistry includes a lengthy treatment of the Bohr atom with little of later developments, and a descriptive and very brief chapter on carbon chemistry. Indeed, a somewhat critical chemist who examined the book was convinced that it must have been written by a physicist; on the other hand, a physicist was especially impressed by the section on the Earth sciences.

In a course of this nature, omissions are inevitable and must be welcomed. The debate must concern the criteria for inclusion and the author would seem to have had the question "What must I include?" in mind rather than the desperate "What dare I leave out?". Designers of new courses which the coming revolution in the sixth form will enforce would do well to follow his example in this respect. But it is to be hoped that no course developed on this side of the Atlantic would carry so little evidence that laboratory work by the student is an essential part of education in science.

MODERN IDEAS IN CALCULUS

Theoretical Analysis

By Lester J. Heider and James E. Simpson. (Saunders Mathematics Books.) Pp. xii+379. (Philadelphia and London: W. B. Saunders Company, 1967.) 59s. 6d.

THE Committee on the Undergraduate Program in Mathematics (USA) has recommended a course in calculus which shall emphasize the logical structure and the nature of mathematical proof. The authors of the present text, while attempting to meet this requirement, are careful to

explain that their book does not replace standard texts in advanced calculus, for skill in technique and applications must still be acquired; overemphasis of abstract concepts may reduce the average undergraduate to mathematical sterility. The reader is expected to have had at least a good first course in calculus.

The underlying notion is that of functional analysis, in metric or normed spaces. Thus the first six chapters lead to the Riemann and Riemann–Stieltjes integrals, as providing an ordered linear topological space with a norm (the integral) determining its topology. But this space is not complete, and the next step is to embed this space in a complete space by means of the Lebesgue integral. From the L^2 space, Hilbert space is easily reached in a chapter which goes as far as the famous functional extension theorem of Hahn and Banach. There is a short chapter on multiple integrals, and a final chapter tracing connexions with classical calculus: orthogonal polynomials, the Fredholm integral equation, the spectrum of a self-adjoint operator.

This is a very stimulating volume; but stimulants must be employed with care, and an external motivation might have to be strongly urged to save the weaker students from a hangover. The honours undergraduate interested in pure mathematics should be able to digest most of the book readily enough, especially as the discussions in the earlier chapters are taken quite slowly and in full detail. The authors also hope that teachers of mathematics in schools may find help here in bringing their knowledge up to date.

T. A. A. Broadbert

ELECTRON DIFFRACTION

Interpretation of Electron Diffraction Patterns

By K. W. Andrews, D. J. Dyson and S. R. Keown. Pp. xi+188+5 plates. (London: Hilger and Watts, Ltd., 1967.) 105s. net.

This book is intended for those who observe high energy electron diffraction patterns, particularly in a transmission electron microscope.

The first section contains sixty-three pages devoted to the theory and interpretation of electron diffraction patterns from crystalline materials. When discussing the determination of unknown crystal structures the authors only consider numerical methods and make no reference to Bunn charts. Moiré fringes are mentioned but are not explained. This subject is of sufficient impertance to merit detailed consideration. Alternatively a reference should have been made to a suitable book such as that by Hirsch et al.¹. The subject matter of this section is not always presented in a manner which would be readily intelligible to a beginner; for example, Laue zones and reciprocal lattice streaks are discussed before the intensity formula is given from which such effects may be deduced.

The second section contains seventy-seven pages of well presented information about plane spacings, interplanar and interzonal angles, angles required for the construction of stereographic projections and standard diffraction patterns with and without double diffraction. The information applies to tetragonal, hexagonal, rhombohedral and cubic crystals. Allowed diffraction maxima are listed for the various cubic lattices (primitive, b.c.c. and so on) and many stereographic projections are given. These illustrate, among other things, twinning in cubic crystals and the various inter-relations between lattices in martensitic transformations. A table of electron scattering factors is not given.

The third section contains information of the type given in the previous section, but it applies to specific materials such as metals, metallic carbides and intermetallic compounds. The relation between cementite and ferrite is considered. The book, which concludes with a description of a stereographic plotting table, contains fifty-seven references and an adequate index. It is a useful addition to the literature of high energy electron diffraction.

THEORETICAL PLASMA PHYSICS

Theoretical Methods in Plasma Physics

By N. G. van Kampen and B. U. Felderhof. Pp. ix + 215. (Amsterdam: North-Holland Publishing Company, 1967.) 160s.

THE authors do themselves less than justice in their preface to this book. They imply that this is a book for the theoretical rather than the plasma physicist, in which plasma physics is seen not so much as a subject in its own right but rather as a vehicle on which to exercise a variety of theoretical methods. This generated, for me, a bias against the book which was only dispelled when going through the text.

It is true that such a formal approach leads to an emphasis on general consequences at the expense of those details which yield a physical insight into plasma behaviour, but this fault is partly overcome by the choice of explanatory problems (with hints on their solution) which occur appropriately throughout the text and not

at the end of the chapters.

The authors admit that they have chosen topics which strongly reflect their own research interests; they are known for their work on the Vlasov equation and discuss this extensively together with its application to plasma wave theory. On the other hand, such subjects as turbulence and radiation emission, where the insight and guidance of theoreticians are so valuable, are missing.

A plasma is treated initially as a continuum fluid; the equations of magnetohydrodynamics are developed and solutions, dependent on and independent of time, are discussed, as well as instabilities. The rest of the book considers the plasma in terms of individual particles. Three chapters on the statistical mechanics of an ionized gas, two component and multi component theory, are followed by five chapters based on the Vlasov equation.

A theoretician reading himself into plasma physics could well start with this book; it can also be recommended to any worker in this field as a theoretical treatment to be followed without too much difficulty.

JOHN PAIN

QUANTUM MECHANICS AND NMR

Structure of High-Resolution NMR Spectra

By P. L. Corio. Pp. xi+548. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1966.) 120s.

This well produced volume results from the expansion of a widely read review article which appeared in 1960. The first eight chapters deal with the theory, which is illustrated by some opportune examples, of single quantum transitions in the presence of a linearly polarized rf field. The final chapter provides an introduction to multiple quantum transitions, double resonance and a new section on spin-echo experiments. A collection of numerical data for some two-group systems forms an appendix. This is based on the original article, but it should be noted that the numbering of some of the transitions has changed and a new spin system, A₄B, has been added.

All of the mathematical apparatus required for the analysis of high resolution nuclear magnetic resonance (NMR) spectra is thoroughly developed. Few books adequately cover this aspect of the subject, and so this

volume should appeal to research workers who may wish to advance their knowledge of quantum mechanics and applications to high resolution NMR. It should also be stated that the mathematically inept will not find it easy reading on the first occasion.

It is unreasonable to expect the theoretical and practical aspects of the subject to be treated in depth in a single volume, and so it is appropriate for this book to concentrate on the former and leave the more detailed aspects of the latter to others. The book has adequate author and subject indices and each chapter has a bibliography, but there is no reference to spin systems containing more than three groups of nuclei.

On the understanding that the book could be used either in a course in high resolution NMR or in an elementary course in quantum mechanics it is to be recommended.

G. A. WEBB

FAILURE OF A MISSION

Crganic Chemistry of Macromolecules

An Introductory Textbook. By A. Ravve. Pp. xiii + 498. (London: Edward Arnold (Publishers), Ltd.; New York: Marcel Dekker, Inc., 1967.) 126s. net.

In his preface the author sets out his objectives in writing this book. It is intended to be an introductory textbook covering "the most important and interesting aspects of organic chemistry of macromolecules" which, it is anticipated, "will be useful in an advanced course in polymer chemistry". "Some brief excursions into physical chemistry (kinetics, molecular weight determinations, and so forth) are undertaken to facilitate the discussions." "No attempt has been made to present an exhaustive review of the literature. What is offered instead is a selection of references which will present each subject; this was done, of course [sic], in an arbitrary fashion." "Greater attention is given to synthetic macromolecules than to naturally occurring ones. This is done on the assumption that most organic chemists are more concerned with synthetic materials."

Many readers will be disappointed at the scant treatment allotted to natural macromolecules (fifteen pages on polysaccharides, nineteen on proteins, seven on polynucleotides) and all will be alarmed at the admittedly apparently arbitrary selection of references. Nevertheless, a really good guide to the organic chemistry of synthetic macromolecules, a subject so important to the chemical industry and so neglected in most university courses, is badly needed and in undertaking the writing of such a book the author gave himself an opportunity of making chemistry and chemists deeply indebted to him. Unfortunately, he has not succeeded in his task and the book he set out to write still needs to be written.

The general plan of the book (an introduction, mainly on physical properties; mechanisms of polymerization reactions; addition polymers; condensation polymers; naturally occurring polymers; reactions of polymers) is

good, but its execution is not.

The book contains, without doubt, a mine of information on its subject; unfortunately the mine has not been worked. The presentation is unclear, jumbled and confused; for example, the third chapter, on the molecular weights of polymers, leaves one little wiser after reading than one was before. The following verbatim quotations are a few examples of obscurity: page 3, "The opinion of the majority of that day was that Raoult's solution does not apply to materials in colloidal state"; page 33, "At that point the minimum takes an upturn"; page 40 "Thus arises the need to work with concentrations below 1 per cent and in many cases down to several tenths o 1 per cent"; page 111, "Ethylene was then bubbled into this suspension for perhaps 30 minutes, sometimes a room pressure or at a few atmospheres"; page 113

"Generally, most such heterogeneous systems are active at relatively high temperatures (room to 100° C)". There are also plenty of what I assume to be uncorrected misprints, for example on page 24, "polyacrylonite"; page 39, "a polymer of glucose ($C_6H_{12}O_{6n}$); and page 47, "where π is the constant 3·214". I am reminded of the first draft of a PhD thesis by a student whose native tongue is not English. Such a student is made to rewrite and rewrite; it is a pity the publishers did not demand as much of the author of this book.

Far from being stimulated by this book, those who read it are more likely to be repelled, and what might have been a real service to organic chemistry has a good chance of turning out to be a real disservice. The best one can hope is that this book will quickly be forgotten and that someone else will do what this author has so singularly failed to do.

H. N. RYDON

MORE SNELL AND SNELL

Colorimetric Methods of Analysis

Including Photometric Methods. Vol. 4A. By Foster Dee Snell and Cornelia T. Snell. Pp. ix+645. (Princeton, N.J.: D. Van Nostrand Company, Inc.; London: D. Van Nostrand Company, Ltd., 1967.) 140s.

Any analyst who has to deal with a wide diversity of samples and finds colorimetric or spectrophotometric methods sufficiently accurate for his purpose is bound to have Snell and Snell within arm's reach of his bench. Others who have occasional need to deal with samples outside the narrow range of daily routine will have Snell and Snell on their library shelves. And it is to Snell and Snell that the analyst will first refer colleagues seeking advice on particular determinations. This work is, in short, the established source for analytical procedures based on colour reactions. Such are the convenience and popularity of spectrophotometric methods that the flow of papers describing new methods or reagents or determinations of new products or of old products in new contexts continues to increase. To keep abreast of the literature is a formidable task indeed, while to make any sort of critical evaluation is wellnigh impossible. Developments in the subject have, of course, meant that some of the material in the four original volumes of this work has been superseded by improved methods or new methods, and advances in science and technology have posed new problems, solutions to which are not to be found in the early volumes of this edition. The heroic feat of updating the second and third volumes has been completed, and is here in part accomplished for the fourth volume. But so extensive is the literature to be covered that it has been found necessary to split the supplementation of this fourth volume into two parts, and volume IVA covers the advances of the past twelve years relevant to the first seven chapters of volume IV, dealing with organic compounds of non-cyclic nitrogen. The six chapters deal with nitrates, nitrites and nitro compounds; aliphatic amines and amides; amino-acids; proteins; aromatic primary, secondary and tertiary amines and amides; and azo compounds, nitrogen containing cycles and other systems. A selection has been made of some 1,383 references for detailed treatment, but many more citations are made in

The treatment is terse and severely practical. General discussion is sharply pointed and principles are stated with the utmost economy. Sample treatment and determination procedure for each compound are given tersely but in full working detail such that a technician, in consultation with an analyst during the initial stages, can work directly from the text. The wealth of information compressed into this volume makes it very good value, and it will be particularly welcomed by clinical, pharmaceutical, agricultural, public health and biochemical

workers as well as by organic chemists in general. Neither praise nor criticism of so compendious a work is viable, one can only admire and return thanks for the industry of the authors and the high standard they have maintained.

E. BISHOP

AUTOIMMUNITY

Autoimmunity: Clinical and Experimental

By J. R. Anderson, W. W. Buchanan and R. B. Goudie. (A Monograph in the Bannerstone Division of American Lectures in Living Chemistry.) Pp. xv+485. (Springfield, Illinois; Charles C. Thomas, 1967.) \$19.50.

The great expansion of interest in all aspects of immunology which has occurred during the last decade has been particularly dramatic in the case of autoimmunity which appeared so paradoxical to the classical immunologist. It would be premature to suggest that this paradox is completely resolved, yet it is obvious that the study of autoimmunity promises to be very fruitful to the immunologist and is also becoming increasingly relevant to clinical medicine. This new book by three of the Glasgow group who have contributed so much to the development of the subject reflects the diversity of the problems as well as the variety of disciplines which autoimmunity encompasses.

Although the subject matter is necessarily similar to that of other recent books on autoimmunity, the organization of the material is somewhat novel. The book is in three sections, the first of which is mainly concerned with the fundamentals of immunology and autoimmunity. The basic concepts and nomenclature of immunology are introduced in a clear and simple way before the experimental and theoretical aspects of autoimmunity and its relation to disease are considered in more detail. Possible mechanisms of autoimmunity are then discussed with particular regard to the role of the thymus.

The correlation of autoimmunity with disease occupies the rest of the book and is divided between the organspecific diseases and the connective tissue diseases. Work on all the immunological aspects of these diseases is thoroughly surveyed and where possible significant correlations are made. The total amount of information is very great, but there is still insufficient evidence to allow firm conclusions to be drawn about the pathogenesis The authors, however, have of autoimmune disease. critically assessed the relevance of the existing evidence and have been able to draw limited conclusions. Further progress has been achieved since this book was prepared, but this does not substantially detract from an excellent survey of the subject presented in a clear and stimulating style. The printing and photographic reproductions are excellent and the twelve hundred references should provide J. E. FOTHERGILL adequate further reading.

INSIDE HYDRA

The Cell Biology of Hydra

By Th. L. Lentz. Pp. xi+199. (Amsterdam: North-Holland Publishing Company, 1966.) 40 guilders; 80s. This is primarily a research monograph recounting the author's own observations. While these are mainly concerned with the fine structural morphology of hydra, there is material on enzyme histochemistry, nematocyst discharge and the role of the nervous system in regeneration. The author thus does not attempt to provide a balanced review of the cell biology of hydra and he is very uncritical not only of his own work but also of that of others. For example, when dealing with regeneration and growth of hydra, he presents, in the main, only his observations which he suggests point to the presence of a growth stim-

ulating or form regulating substance in neurosecretory granules, which is intimately involved in growth and regeneration. This view is based in part on the effect of neuropharmacological agents on regeneration, which I would regard as remarkably unimpressive and inconclusive. The most useful material in the book is the electron microscope observations, which provide a convenient and detailed structural description; the summarizing diagrams are particularly clear. There are also some interesting suggestions and observations on the control of nematocyst discharge.

For the research worker dealing with hydra this is quite a useful but uninspiring book. It cannot be recommended for other biologists. The many cell biology problems posed by hydra remain largely unexplored and even the problems of form, growth, regeneration, behaviour, communication and osmoregulation are undefined. If one is to write a book on a topic of considerable interest based mainly on one's own research work, then this work ought to be seminal, or at least well above average. The work described here is not.

L. WOLPERT

TRACKING BRITISH MAMMALS

Mammals of Britain

Their Tracks, Trails and Signs. By M. J. Lawrence and R. W. Brown. Pp. 223+32 plates. (London: Blandford Press, 1967.) 30s. net.

APPEARING so soon after the Handbook of British Mammals, a new book on the subject calls for some justification by way of fresh information and novel treatment. useful book passes the test by reason of its concentration on drawings of the footprints and droppings of mammals and inclusion of many more drawings of skulls and teeth. The basic information about each species being less than is given in the Handbook, one still inevitably turns to the latter as a reference book, but Lawrence and Brown have produced a handy companion to the larger work. Another different feature is the distribution maps given for some (but not all) of the wild species (domestic animals are also included). These, I feel, do not always come off; some of them, such as otter, pine marten, Leisler's bat and mole. merely illustrate how very difficult it is to put imperfect information into map form. The authors are not, of course, to blame for the imperfection of the information, which is the fault of all British mammalogists, but they have tended to give an impression of precision where vagueness should have been the order of the day. And an attempt to show vagueness on a map usually ends in

I am also struck by how hard it is nowadays to produce a really up to date book on British wildlife. New facts are constantly emerging or being discovered, and no book can be completely up to date, even given perfect distribution of new knowledge. In this book, for instance, one naturally looks first to the mink, the grey long-eared bat and the coypu, and in each case events have moved on since the book was written, doubtless 18 months or so before it was published. But by the same token the authors are that much more up to date than the *Handbook*, published in 1964.

R. S. R. Fitter

OBITUARIES

Sir Cyril Hinshelwood

Sir Cyril Hinshelwood died at his London home during the evening of October 9. A few hours earlier he had talked with one research student and had written to another to arrange a discussion about a joint publication His death came as a shock to his many friends who have seen him so relaxed and happy during recent years when free from administrative duties, he was able to enjoy his laboratory work and pursue his many other interests.

Hinshelwood was recognized internationally as one o the finest intellects of our time, a polymath, a descendanof those men described in John Evelyn's diary as "My lords virtuosi"—the early Fellows of the newly born Royal Society, over which he was to preside with distinction. Born in 1897, he was educated at Westminster City School, went to Balliol College, Oxford, in 1919 with a Brackenbury scholarship, and gained distinction in the shortened post-war course in 1920. After a year as a fellow of Balliol, he became a fellow and tutor of Trinity and in 1937 succeeded Professor F. Soddy as Dr Lee's professor of physical and inorganic chemistry. On retirement in 1964, he returned to his native London as a senior research fellow of Imperial College. During his professorship, physical chemistry at Oxford reached full bloom. The move was made from the cellars and outhouses of Trinity and Balliol to new laboratories, and among his staff were nine Fellows of the Royal Society leading research groups in diverse fields.

From 1916-19 he worked at the Queensferry Royal Ordnance factory on explosives, where his remarkable ability was quickly noticed. This work stimulated his interest in the mechanisms of chemical change, which was to be the main theme of nearly all his scientific research. Throughout, he showed a mastery in planning simple measurements to answer questions of great complexity. His earliest papers dealt with the velocity of decomposition of solid substances and of reactions of gases on metallic catalysts. He soon turned to homogeneous gas reactions with special reference to theories of molecular In 1926 he interpreted some first order activation. decompositions of organic molecules as quasi-unimolecular processes involving activation by collisional mechanisms. Soon afterwards, from kinetic measurements he established the main characteristics of thermal chain reactions. The discovery of critical explosion limits, similar to those found by Semenov in other systems at about the same time, led to new ideas about straight and branching chains. The effects of catalysts such as iodine on some of these gas reactions, of inhibitors such as nitric oxide or propylene, and of deuterium were used to clarify other details. In those early years, the origin and nature of the chain carriers were obscure, and Hinshelwood sought, with meticulous care, to establish their identity. final account of the hydrogen-oxygen reaction, given in the Bakerian lecture (1946), was the culmination of a long exemplary application of the scientific method to disentangle the intricacies of this process. Later, he studied the mechanism of thermal decomposition of hydrocarbons, and the polymerization of some unsaturated compounds. Over many years, too, he examined the kinetics of a variety of reactions in non-aqueous solvents and in the liquid phase. Here again, the main aim was to establish the significance of the constants in the Arrhenius equation and the functional relationships between them. He analysed the different approach in his own work and that of others using the so-called transition state theory, but emphasized clearly the fundamental relationships between the different methods. His book on The Kinetics of Chemical Change appeared, in a kind of evolutionary way, in four editions between 1926 and 1940.

In 1938 he used the kinetic approach to study physicochemical aspects of bacterial growth, and this subject perhaps remained his major love to the end. The influence of added substances on the different phases of the growth curve, the adaptation of bacteria and their resistance to drug action caused by changes of media, the take-up of alkali metals or of phosphorus and the effect of different carbon sources, were examined. The living cell was con-

ceived as a complex assemblage of chemical reactions, each subject to the same laws. "One of the sources of the each subject to the same laws. "One of the sources of the richness and subtlety shown by the behaviour of living matter," he wrote, "is the way in which, in the individual, physico-chemical laws can play variations on the fundamental theme expressed by the genetic code, while populations can also respond in another way to rarer and more catastrophic changes in the code itself." He discussed these laws in many papers and in two books, The Chemical Kinetics of the Bacterial Cell (1946) and (with A. C. R. Dean) Growth, Function and Regulation in Bacterial Cells (1966). The question of cellular regulation was a recurring theme which found expression in what he called "the principle of total integration" and the "network theorem". These expressed in mathematical terms the mutual interdependence of all the components in the intact functioning cell. He had been asked for a non-mathematical presentation. Two days before his death, he wrote of his intention to do this, "pointing out where, which is in most places, the model is not in conflict with other descriptions, but adds something of its own". He was not unaware that his incursions into biology had encountered some scepticism among a few of the more traditional professional biologists. In his elegant book The Structure of Physical Chemistry (1951) he presented a unified, coherent story in his own critically philosophic way. His first book, Thermodynamics for Students of Chemistry (1926), is another, less known, classic.

Hinshelwood was in turn president of the Chemical Society, Faraday Society, Royal Society, the British Association, and of the Classical Association; chairman of the Research Committee of the Gas Council, a delegate of the Clarendon Press, chairman of the Council of Queen Elizabeth College, London, a trustee of the British Museum, and on the court of the Goldsmiths Company. He served on many governmental advisory committees. His honours included the Davy, Royal, Copley and Leverhulme medals of the Royal Society, the Longstaff and Faraday medals of the Chemical Society, the Nobel Prize for Chemistry (shared with Semenov) and many medals given by foreign organizations. He received honorary doctorates from about a dozen universities, was a member of many foreign academies, and an honorary fellow of four Oxford colleges. In 1960 he received the Order of Merit.

To his fluency in numerous European languages there was added a competence in Russian and Chinese, with a little Arabic. He had a wide knowledge of English and foreign literature, of operatic music, of Chinese porcelain and Persian carpets, and was an accomplished painter in oils. He often contributed papers to the Oxford Dante Society. He was regarded with affection and respect by his colleagues, and by undergraduates in both the sciences and the humanities. In all his lectures and writings there was an unmistakable mark of the natural philosopher. None was more fitted than "Hinsh" to drink the traditional toast of the Royal Society's dining club: "Arts and Sciences". H. W. T.

Dr Pierre Jacquet

PIERRE JACQUET and his wife died tragically at sea near Puerto de la Selva, Spain, during a trip in their cabin cruiser on September 6, 1967. Jacquet was born in 1906 at Saint-Mande (Seine), graduated as a chemical engineer from the Institut de Chimie, Paris, in 1926, and obtained his doctorate in 1938. He was well known throughout the world as the father of electropolishing, a phenomenon which he discovered in association with H. Figour in 1929.

He first described this process in the Comptes Rendus in 1935 (201, 1473), and spent the rest of his scientific life investigating fundamental aspects of the phenomenon, applying it to a wide range of metals and alloys, and encouraging its industrial application. This work is

recorded in more than 200 papers published in many journals in France and elsewhere. It is no exaggeration to say that electrolytic polishing has revolutionized not only the practice of metallography by providing the most scientific way of preparing polished surfaces free from strain and blemishes, but also methods of surface preparation in industry where it is now extensively used for polishing and machining. In addition, the present techniques of electron microscopy of metals and alloys are almost entirely dependent on methods pioneered by Jacquet. In recent years Jacquet developed the technique further so that it could be used in situ on larger structures or objects, thus initiating a new approach in non-destructive metallography. A detailed list of the fields in which Jacquet has made effective contributions would include most of the important aspects of physical metallurgy. Much of his early work was done in the Research Laboratory of the Société, le Materiel Téléphonique, but since 1945 he worked in the Research Laboratory of the French Navy, from which he had only recently retired.

His scientific work has been recognized by many awards including the Berthelot Medal (1956), the Jaffe Prize of the French Academy, and the Le Chatelier Medal of the Société Française de Métallurgie. He was a Chevalier de la Légion d'Honneur and an Honorary Foreign Member of the American Academy of Arts and Sciences (1956).

Jacquet will be long remembered as a modest, retiring man who by firm conviction and a long scientific career at the laboratory bench made outstanding contributions to metallurgical science and technology.

R. W. K. HONEYCOMBE

Dr Francis Silsbee

Francis Briggs Silsbee, who died on August 21, aged 78, retired as Chief of the Electricity Division of the US National Bureau of Standards in 1959. He had made many contributions to electrical engineering.

Silsbee graduated in electrical engineering from the Massachusetts Institute of Technology in 1910 and obtained a master's degree the following year. In 1915 he obtained his doctorate from Harvard University. He joined the National Bureau of Standards in 1911, and continued to act as a consultant after his retirement, when he was interested in the history of the scientific work of the bureau. He was chairman of a committee whose work led to the establishment of the NBS Museum. which exhibits instruments made during the 66 years of the bureau's existence.

Silsbee's contributions to electrical engineering included involvement in the design of alternating current resistors of exceptionally low reactance. He also invented the test set which is used by industry to compare working current transformers with standard transformers of known ratio and phase angle. During the Second World War, he investigated lighting hazards to aircraft for the National Advisory Committee of Aeronautics. As chief of the Electricity Division at the National Bureau of Standards he was concerned with establishing electrical units and standards, and took part in committee work with the International Electrotechnical Commission and other standardizing organizations. In 1956 Silsbee was sent to Ethiopia by the International Co-operation Commission to advise the government on the establishment of a national system of measurement standards.

Silsbee was a fellow of the Institute of Electrical and Electronics Engineers, a fellow of the American Physical Society, and a former president of the Washington Philosophical Society and the Washington Academy of Sciences. In 1963 he received the Morris E. Leeds Award for his contribution to the methods of improving the accuracy of commercial electrical measurements. He also received Exceptional Service Awards from the Department of Commerce and the Naval Bureau of Ordinance.

University News:

Bristol

DR J. B. CHAPPELL, reader in biochemistry in the university, has been appointed to the second chair of biochemistry, and Professor D. L. Dinely, professor and chairman of the Department of Geology in the University of Ottawa, has been appointed to the Chaning Wills chair of geology.

Liverpool

DR A. D. BRADSHAW, reader in agricultural botany in the University of North Wales, Bangor, has been appointed to the Holbrook Gaskell chair of botany, and Dr H. D. Parbrook, at present reader in charge of the Department of Building Science at Liverpool, has been appointed to the chair of building science.

Sussex

MR J. F. Scott, at present reader in mathematics and statistics at the university, has been appointed to a personal chair of applied statistics.

Weizmann Institute of Science

PROFESSOR M. FELDMAN, dean of the institute's Feinberg Graduate School, has been appointed the first holder of the Klutznick chair in developmental biology. This chair was established in honour of Mr P. M. Klutznick on his sixtieth birthday.

Appointments

DR S. C. DAUBIN, head of the Marine Sciences Section of General Motors Corporation at Santa Barbara, California, has been appointed senior scientist and chairman of the Department of Ocean Engineering in Woods Hole Oceanographic Institution.

Announcements

PROFESSOR P. M. S. BLACKETT has been appointed a member of the Order of Merit, the tenth scientist of a possible membership of twenty-four.

SIR ERIC ASHBY, vice-chancellor of the University of Cambridge and Master of Clare College, has accepted an invitation to become president of the Society for Research into Higher Education, in succession to Lord Fulton. Sir Eric will take the chair at the society's third annual conference to be held in Senate House, University of London, on December 14.

THE inaugural meeting of the Fisheries Society of the British Isles was held on October 21 at the Zoological Society of London and the following officers were elected: President, Dr J. W. Jones; Vice-president, Mr P. H. Tumbleson; Secretary, Dr L. E. Mawdesley-Thomas; Treasurer, Mr A. Wheeler. The society's first meeting will be on April 26, 1968, at the Zoological Society and further details can be obtained from the Hon. Secretary, Department of Pathology, Huntingdon Research Centre, Huntingdon.

THE Royal Society has awarded the three Royal Medals for the current year to the following: Professor C. E. Tilley, emeritus professor of mineralogy and petrology in the University of Cambridge, for his contributions in all branches of petrology; Professor J. Z. Young, professor of anatomy in University College, London, for his researches correlating neural structure with function; Sir Joseph Hutchiason, Drapers professor of agriculture in the University of Cambridge, for his work on the genetics and evolution of crop plants with particular reference to cotton.

THE president and the council of the Royal Society have awarded the following medals: the Copley Medal to Professor B. Katz, professor of biophysics at University College, London, for his contributions to knowledge of the fundamental processes involved in transmission across the neuromuscular junction; the Davy Medal to Professor V. Prelog, head of the Laboratory of Organic Chemistry, Eidgenössische Technische Hochschule, Zurich, for his work in the development of stereochemical concepts and on the structure of alkaloids and antibiotics; the Buchanan Medal to Sir Graham Wilson, director of the Public Health Laboratory Service of England and Wales from 1941-63, for his work on the medical aspects of bacteriology and immunity; the Sylvester Medal to Professor H. Davenport, Rouse Ball professor of mathematics in the University of Cambridge, for his contributions to the theory of numbers; the Hughes Medal to Dr K. A. G. Mendelssohn, reader in physics in the University of Oxford, for his contributions to cryophysics, especially his discoveries in superconductivity and superfluidity.

THE Ramsay Memorial Fellowships Trustees will consider in March 1968 applications for one Ramsay travel grant not exceeding £350 for the year 1968–69. The grant will be limited to junior academic chemistry staff of universities and colleges of technology or advanced technology in Scotland. Further information can be obtained from the Joint Honorary Secretaries, Ramsay Memorial Fellowships Trust, University College London, Gower Street, London WC1.

CORRIGENDUM. In the communication "Tetragonal and Hexagonal Iron–Manganese Carbides" by M. J. Duggin (Nature, 216, 362; 1967), the heading of the eighth column of Table 4 should be a, of the fourth and ninth columns should be c and of the tenth column should be a/c. The penultimate sentence of the last paragraph should refer to an "increase of approximately 15·3 per cent in the cell volume of the hexagonal carbide".

ERRATUM. In the article "Amide Cotton Effects of Heparin" by Audrey L. Stone (Nature, 216, 551; 1967), refs. 1–5, not 2–5, should be mentioned at the end of the third paragraph. In the third line of the legend to Fig. 1, 30 sec/period should read 30 sec pen-period. In the fifth line of p. 553 absorption should read rotational, and the sentence beginning on the twenty-third line of the next paragraph should end ". . . however, at low ratios of histamine to heparin the ORD changes in the π - π region are similar to those with decreasing pH".

EBRATUM. In the article "More About Chain Initiation". by our Cell Biology Correspondent (Nature, 216, 638; 1967), the seventh sentence of the second paragraph should have read "Once the initiation complex has formed, a 50S sub-unit couples with it to produce a 70S ribosome attached to mRNA and with the chain initiator in place."

ERRATUM. In the issue of November 4 (Nature, 216, 425; 1967) Professor R. J. Smeed was misquoted as saying that road accidents cause 8 per cent of all male deaths. Although the proportion varies widely—and is as high as 50 per cent in the 15 to 19 age group—only 2 per cent of all male deaths are caused by road accidents.

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Monday, November 27

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2) -Colloquium on "Energy from Natural Gas".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W1), at 1.15 p.m.—Professor L. Pearce Williams: "Physics and Philosophy in the Early Nineteenth Century".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 5.30 p.m.—Dr C. S. E. Phillips: "Computers and Adaptive Radar".

INSTITUTION OF ELECTRICAL ENGINEERS (Joint meeting with the Automatic Control Group of the Institution of Mechanical Engineers, at 1 Birdcage Walk, Westminster, London, SW1), at 6 p.m.—Discussion Meeting on "Systematic Approach to Design" opened by Mr R. L. Latham and Mr G. J. Terry.

Tuesday, November 28

ROYAL INSTITUTION (at 21 Albemarle Street, London, W1), at 1 p.m. Dr W. H. Brock: "William Bollaert, Faraday and the Royal Institution".

UNIVERSITY OF LONDON (at Imperial College of Science and Technology, London, SW7), at 1.30 p.m.—The Reverend Professor C. F. Evans: "A Scientific View of the Gospels" (further lectures on December 5 and 12).*

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 5.30 p.m.—Discussion Meeting on "Coding in the Visual Nervous System" opened by Mr A. Robertson.

ROYAL INSTITUTION (at 21 Albemarle Street, London, W1), at 5.30 p.m.— Sir Lawrence Bragg, FRS: "How we Hear, Speak and See". (Lecture for Sixth Form Boys and Girls from Schools in London and the Home Counties. To be repeated on November 29, and December 5 and 6.)

UNIVERSITY OF LONDON (at the Institute of Child Health, Gullford Street, London, WG1), at 5.30 p.m.—Dr V. Eisen: "Kinin Formation in Human Disease". (Thirteenth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)*

INSTITUTION OF ELECTRICAL ENGINEERS, LONDON GRADUATE AND STUDENT SECTION (at Watford College of Technology, Watford), at 6.30 p.m.—Mr F. J. M. Laver: "Computers".

SOCIETY FOR ANALYTICAL CHEMISTRY, PARTICLE SIZE ANALYSIS GROUP (in the Physics Lecture Theatre, Imperial College, London, SW7), at 6.30 p.m.—Second Annual General Meeting, followed by an Ordinary Meeting on "Light Scattering Methods".

Tuesday, November 28-Wednesday, November 29

INSTITUTE OF WATER POLLUTION CONTROL (at Church House, Westminster, London, SW1)—Symposium on "Water Pollution Control".

Wednesday, November 29

SOCIETY FOR ANALYTICAL CHEMISTRY, THIN LAYER CHROMATOGRAPHY GROUP (at the Borough Polytechnic, Borough Read, London, SE1), at 2.15 p.m.—Third Annual General Meeting, followed by Scientific Papers.

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, WC2), at 2.30 p.m.—Mr G. Ordish: "Scientific Pest Control and the Influence of John Curtis" (John Curtis "Woodstock" Lecture).

INSTITUTION OF MEGHANICAL ENGINEERS, LUBRICATION AND WEAR GROUP (joint meeting with the Institute of Physics and the Physical Society; the Institution of Metallurgists; and the Royal Institute of Chemistry, at 1 Birdcage Walk, Westminster, London, SWI), at 4 p.m.—Discussion Meeting on "Tribology—Its Inter-Disciplinary Challenge".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 5.30 p.m.—Mr D. J. Williams, Mr L. J. Allen and Dr T. A. Davies: "Contacts in Telephony—a Search for the Ideal".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 5.30 p.m.—Mr W. J. Nicholls and Mr F. G. McDonald: "Aluminium Conductors for Overhead Lines".

UNIVERSITY OF LONDON (In the Anatomy Theatre, University College. Gower Street, London, WC1), at 5.30 p.m.—Dr G. A. Horridge: "The Compound Bye: Being an Analysis of what Arthropods See, as based upon the Electrophysiological Analysis of the Retina of Apposition Eyes and of the Optokinetic Response" (further lectures on November 30 and December 1).*

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS (at 8-9 Bedford Square, London, WC1), at 6 p.m.—Professor K. W. H. Stevens: "Generation, Propagation and Applications of Microwave Acoustics".

UNIVERSITY OF LONDON (at the Institute of Neurology, National Hospital, Queen Square, London, WC1), at 6 p.m.—Mr V. Logue and Dr H. Davson: "Cerebrospinal Fluid: Hydrocephalus and Mechanics—Clinical and Biochemical Aspects".

Thursday, November 30

ROYAL INSTITUTION (at 21 Albemarle Street, London, W1), at 2.30 p.m. Professor R. J. Harrison: "The Living Cell" (Civil Service Lecture).

ROYAL SOCIETY (at 6 Carlton House Terrace, London, SW1), at 2.30 p.m.-Anniversary Meeting.

UNIVERSITY OF LONDON (at the Institute of Child Health, Guilford Street, London, WC1), at 5.30 p.m.—Dr D. A. Price Evans: "Genetic Factors in Drug Therapy". (Fourteenth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)*

Institution of Mechanical Engineers, Steam Plant Group (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p.m.—Discussion Meeting on "Planning and Progressing in Site Construction".

SOCIETY OF CHEMICAL INDUSTRY, OILS AND FATS GROUP (at 14 Belgrave Square, London, SW1), at 6.15 p.m.—Dr A. Spicer: "Fats in the Baking Industry".

UNIVERSITY OF LONDON (at Wye College, Wye, near Ashford, Kent), at 8.15 p.m.—Miss Sylvia Crowe: "Design for a Changing Landscape".*

Thursday, November 30-Friday, December 1

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (at the Institution of Electrical Engineers, Savoy Place, London, WC2)—Symposium on "Photographic Granularity".

Friday, December I

INSTITUTE OF BIOLOGY (in the Wellcome Lecture Hall, Royal Society. 6 Carlton House Terrace, London, SW1), at 10.30 a.m.—Conference on "Improving the Contacts Between Industry and University".

ROYAL INSTITUTION, PHOTOCHEMISTRY DISCUSSION GROUP (at 21 Albemarle Street, London, W1), at 1 p.m.—Dr B. Broklehurst: "The Naphthalene Dimer Cation $(C_{10}H_9)^+_3$ ".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2). at 5.30 p.m.—Dr A. Fettweis: "Resonant Transfer".

INSTITUTION OF ELECTRICAL ENGINEERS (joint meeting with the Automatic Control Group of the Institution of Mechanical Engineers, at Savoy Place, London, WC2), at 5.30 p.m.—Mr D. D. Lipman: "Experiments in the Use of Digital Systems for Air Traffic Control at the Eurocontrol Experimental Centro".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W1), at 9 $\rm p.m.$ -Professor Hermann Bondi, FRS: "Gravitation".

Saturday, December 2

BRITISH MYCOLOGICAL SOCIETY (at the Linnean Society of London, Burlington House, Piccadilly, London, W1), at 2 p.m.—Annual General Meeting. followed by Professor J. L. Harley, FRS: "Fungal Symbiosis" (Presidential Address)

Iollowed by Professor J. L. Harley, Eds. Funga: Symbols (Address).

INNER LONDON EDUCATION AUTHORITY (at the Horniman Museum, London Road, Forest Hill, London, SE23), at 3.30 p.m.—Miss P. M. Sears: "George Baxter of Sydenham—the Victorian Colour Printer".*

Monday, December 4

INSTITUTION OF ELECTRICAL ENGINEERS (joint meeting with the Institution of Heating and Ventilating Engineers, at the Institution of Electrical Engineers, Savoy Place, London, WC2), at 5.30 p.m.—Discussion Meeting on "The Commissioning of Engineering Services in Large Buildings" opened by Mr P. A. Flanigan and Mr W. C. Jeffreys.

SOCIETY OF ENGINEERS (at Burlington House, Piccadilly, London, W1), at 6 p.m.—Mr Brian J. Bell: "Reinforced Plastics".

SOCIETY OF CHEMICAL INDUSTRY, LONDON SECTION (at 14 Belgrave Square, London, SW1), at 6.30 p.m.—Professor C. F. Cullis: "Recent Developments in the Controlled Oxidation of Hydrocarbons".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:
GRADUATE IN BIOCHEMISTRY (or other biological subjects with a wide general interest in biology) in the DEPARTMENT OF MEDICINE, for research work on the synthesis or secretion of hormones—The Secretary, King's College Hospital Medical School, Denmark Hill, London, SE5 (November 30).

HRAD TECRNICIAN (preferably with experience in both human and animal physiology) in the DEPARTMENT OF PHYSIOLOGY, University of Nottingham Medical School—The Registrar, The University, Nottingham (November 30).

ASSISTANT LECTURER (with special qualifications or interests in pharmaceutical chemistry) in PHARMACY—The Registrar, University of Manchester. Manchester, 13, quoting Ref. 169/67Na (December 2).

BRITISH EMPIRE CANCER CAMPAIGN RESEARCH WORKER (science graduate with experience in cytogenetics) to be a senior member of a small team working on problems related to leukaemia—The Secretary, King's College Hospital Medical School (University of London), Denmark Hill, London, SE5 (December 2).

LECTURER (preferably graduate in veterinary medicine, pharmacology or physiology) in Veterinary Pharmacology—The Secretary of the University Court, The University, Glasgow (December 4).

LABORATORY MANAGER (with previous laboratory and administrative experience) to be responsible for the supervision of all laboratory services. Including stores, assist in recruitment and training, and the general supervision of junior laboratory staff and to maintain liaison with the Institute service departments—The Secretary, Animal Virus Research Institute. Pitright, Surrey (December 5).

LECTURER IN THE DEPARTMENT OF PHYSICS, University of the Witwaters and, Johannesburg, South Africa—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (South Africa and London, December 8).

LECTURER (With an honours degree in civil engineering and at least five years' professional experience, and preferably experience in the use of

The Secretary of the University Court, The University, Glasgow (December 15).

Lecturer of Assistant Lecturer in the Department of Mathematics—The Secretary, University of Edinburgh, Old College, South Bridge Edinburgh (December 15).

Lecturers/Assistant Lecturers (with at least a good honours degree or equivalent, plus suitable teaching and research experience) in Chemistry at the University of Malaya—The Association of Commonwealth Universities (Branch Office), Mariborough House, Pall Mall, London, SW1 (Kuala Lumpur and London, December 17).

Research Assistants (2) in the Department of Ceramics with Refractories Technology, for a programme of research into the factors controlling the constitution and microstructure of polyphase ceramics and the influence of these variables on their temperature properties, including hot strength and creep resistance—The Registrar, University of Sheffield, Sheffield (December 22).

CHAIR OF BIOCHEMISTRY—President of the Board of the Swiss Federal Institute of Technology, CH-8006 Zurich, Switzerland (December 31).

SCIENTIFIC OFFICIER (with at least a good honours degree in an appropriate agricultural science) for research on methods of growing sugar-beet root and seed crops and assist in managing the farm; and a SCIENTIFIC OFFICIER (with at least a good honours degree in botany or agricultural botany) to study the factors affecting the quality of sugar-beet seed, at Brooms Barn Experimental Station, Higham, Bury St. Edmunds—The Secretary, Rothamsted Experimental Station, Harpenden, Hertfordshire (December 31).

at the London School of Economics and Political Science—The Academic Registrar (N), University of London, Senate House, London, WC1 (March 1).

HEADSHIP OF THE DEPARTMENT AND CHAIR OF PHYSICS—The Academic Registrar, The City University, St. John Street, London, EC1, quoting Ref. P/N.

PINCIPAL LECTURER (preferably with a special interest in bacteriology or virology or some other aspect of microbiology) in Microbiology—The Secretary, Wolverhampton College of Technology, Wolverhampton, quoting Post No. 01305.

Private Science Communication of a Service Science Communication of the Com

Post No. 01305.

PRINCIPAL SCIENTIFIO OFFICER and a SENIOR SCIENTIFIO OFFICER (citizen of the United Kingdom or the Republic of Ireland, preferably with an honours degree in zoology or a medical degree, and postgraduate research experience in tropical parasitology) at the East African Institute for Medical Research, Mwanza, Tanzania, to plan and carry out research on schistosomiasis and methods of control and also to train newly appointed science graduates in research methods—The Ministry of Overseas Development, Room 403 (Y), Eland House, Stag Place, London, SW1.

PROFESSOR OF THEORETICAL CHEMISTRY—Professor R. McIntosh, Head of the Department of Chemistry, Queen's University, Kingston, Ontario, Canada.

HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue.

The direct postal price per subscription for one or two copies of NATURE each week is:

*12 MONTHS (52 issues and 4 indexes)

Great Britain and Eire£14.0.0 ea	ach
United States of America(by air freight)\$48 ea	ach
Canada (by air freight) \$52 ea	ach
Elsewhere overseas by surface mail£14.0.0 ea	ach

(Charge for delivery by air mail on application)
*Shorter periods pro rata. (Minimum three months.)

MULTIPLE SUBSCRIPTIONS

For subscribers who take more than two copies of NATURE each week these reduced annual rates are offered:

12 MONTHS (52 issues and 4 indexes)

Number of	G.B. &			Elsewhere
Copies	Eire			(surface mail)
3–5 6–11 12 or more	Each £13.10.0 £12.15.0 £12.0.0	Each \$46.50 \$44.50 \$42.50	Each \$50.50 \$48.30 \$46.00	Each £13.10.0 £12.15.0 £12.0.0

Multiple subscriptions must run concurrently. Every copy will be posted separately, and for speed of delivery each subscription can be addressed to a different individual, or department at the same address. (ZIP essential for U.S.A.)

NATURE Volume 216 DECEMBER 2, 1967

Is There a Technology Gap?

THE statement by President De Gaulle on November 27 about the prospects for British entry into the European Economic Community is bound to set in train a new flurry of interest in the phenomenon known as the technology gap. Indeed, even without the intervention of the President of France, this well established subject for debate seemed destined for another round of popularity. In Turin two weeks ago, the Twentieth Century Fund and the Agnelli Foundation organized a conference on the subject, and this served as a reminder that it was Signor Fanfani who did much to draw public attention to the technology gap more than a year ago. The council of the EEC has also been taking leisured steps to decide what should be done about technology in Europe, and has produced a declaration of good intentions towards European collaboration in policy making. That development, which followed the meeting of the council in Luxembourg a few weeks ago, seems oddly to have inspired the declaration of Mr Harold Wilson, the British Prime Minister, in his speech at the Guildhall, that the need to close the technology gap, whatever it may be, is now so urgent that he would not wait for British membership of the EEC before taking steps to stimulate more effective collaboration between Britain and the mainland. Nothing much has been heard about the proposal since those brave words were spoken, although the devaluation of sterling is by itself enough to account for that.

A more serious problem, however, is that nobody is quite sure what the technology gap consists of. It is much easier to decide what it is not. For example, it is quite certain that Europe as a whole and European nations individually are not at a disadvantage compared with the United States in their capacity for innovation. That is simply another way of putting the familiar dirge that Europe invents and the United States exploits. It is also plain that the technology gap cannot be measured simply by the numbers of scientists and engineers at work on both sides of the Atlantic. By this simple test, indeed, Britain compares quite well with the United States, and a good many other European countries are not far behind. So why is it that Europe is so much at a disadvantage in the exploitation of new technology? And what can be done to change that state of affairs?

The first thing to acknowledge is that the essential difficulty is somehow to decide which projects to pursue and which to leave alone. This, for example, has been the outstanding problem in Britain since the

Second World War. Should there be a massive investment in aircraft, nuclear energy and computers all at the same time? And what should be done about transport and the development of the chemical indus-Successive governments have been driven by the conviction, now commonly shared in Europe, that it is too dangerous for a forward-looking nation to stand aloof from forward-looking technology of any The result has been that resources have been too thinly spread for new developments to be pushed ahead with the excellence and speed which competitiveness demands. But in the understandable belief that it is necessary at all cost to foster new technologies, by breaking into whatever markets are naturally available to them, successive governments in other European countries as well as Britain have found themselves trying to sell new products in national markets which are too small to be viable on their own. Thus, for example, what really cripples the British aircraft industry is that its domestic market is too small to be profitable. The kinds of nuclear power stations now being built in Britain would be enormously more attractive as commercial propositions if there were a real chance of selling as many again elsewhere. It is sensible also to acknowledge that one awkward accompaniment of this aspect of the problem is that by trying to spread resources over the whole field, European companies have often been less able to manufacture goods of high quality than their American competitors. It is fashionable to blame the supposed spin-off from the programme of space research in the United States for this disadvantage, but that is not an explanation, only an excuse.

It follows from this, of course, that the most certain way-the only long-term way-of making sure that European industries compete with their rivals in the United States is somehow to ensure that European nations can safely be more selective in the jobs they tackle. It must, for example, come to seem quite proper that even the largest of the nations in Europe should be able to refrain from manufacturing aircraft, nuclear power stations, computers or even motor cars. No amount of negotiation between countries on the sharing of technical expertise will help if the partners to these agreements then insist on making everything for themselves. It is true that agreements like these may increase the intellectual productivity of the scientists and technologists concerned, but they will not by themselves allow manufacturing organizations to reap the benefits of concentrated resources and large scale production. This is an awkward truth which everybody, but particularly Mr Harold Wilson, should squarely face. The technology gap is not technological at all but a consequence of the scale and structure of European industry.

Two important principles follow from this, and both of them will be crucial in the years immediately ahead. In the first place, it is doubtful whether there can be much sense in an attempt to anticipate British membership of the EEC by negotiating agreements with European countries on technical collaboration. Indeed, one of the principal objectives of those who formed the EEC in the early 50s was precisely that of finding some device for making the structure of European industry more effective. As the community has emerged, it is precisely the kind of framework within which nations could concentrate their resources on new developments without damaging their pride. Thus the rules of the EEC allow for the free movement of capital and of work-people as well as the more obvious benefits of a market which is as extensive as the whole of Europe.

Yet it remains a sad truth that the EEC has so far been comparatively slow at creating the kinds of institutions needed to exploit these potential advantages of scale. The scale of European communities does not yet match the scale of their opportunities. Regulations of patents and the like are still much in need of co-ordination. Governments still favour companies in their own territories. In other words, it seems as if the EEC itself has still a long way to go along the road to full exploitation of its own resources. In the circumstances, it is hard to see what scope there is for separate action by the United Kingdom.

This raises the issue of what Britain should do if, as seems likely, entry into the EEC is substantially delayed. The first thing to be said is that there is some scope for the fostering of specialization within the framework of the European free trade area. The opportunities for industrial symbiosis with this group may not be as considerable as on the mainland of Europe, but they are not altogether unimportant. But it will also be necessary at some stage for the British interest in advanced technology to become more specialized and concentrated. If this means getting out of aircraft and leaving computers, there will be a good many tears to be shed, yet choices of that kind will be inevitable. It is sensible that the British Government should be looking for bilateral agreements that will help somehow to postpone these nasty decisions but there are obvious limits to what can be done.

Whose Finger on the Drawing-board?

THE first report of the Select Committee of the House of Commons on Science and Technology is not so much a bombshell as a squib. It will startle a good many people, which is by itself not necessarily a disaster. Indeed, by bringing into the open some of the courses of action towards the development of nuclear power in Britain, and towards the Atomic Energy Authority in particular, the select committee has done a public service. Ordinary mortals, like the rest of us, too easily slip into the habit of believing that institutions are assured of a permanent existence once they have provided themselves with the appearances of permanence-headed notepaper, some publicity films and a few laboratories in the country. All this is good, and it is also a great benefit that the Minister of Technology will no longer be able to postpone a decision on the future of the Atomic Energy Authority. Evidently it would have been a great discourtesy if he had rushed ahead with a radical reorganization, although there is a great deal that he could have done in the fields with which the select committee was not con-

If, however, the appearance of the committee's report will pave the way for lasting decisions, there can be little confidence that its own recommendations will quickly be enacted. The trouble is that even though the report itself is packed with the kind of information that will keep specialists poring over it in the months ahead, the argument which sustains the principal conclusions is so lacking in conviction that nearly half of the members of the committee were unconvinced.

In the circumstances, it is only fair to recognize that the committee did successfully cover a good deal of contentious ground. The committee does, for example, take the view that the strategy for atomic energy in the years ahead, in countries such as Britain, should spring from a determination to win the greatest economic benefit. To its credit, the committee is a cheap energy committee, and clearly not overawed by Lord Robens, the chairman of the National Coal Board. There is also a refreshing flavour in its argument that atomic energy should be regarded with some favour because it does less than fuels based on carbon to pollute the atmosphere. These, as the committee quite rightly says, are increasingly important considerations. If this is what foreign travel does for tired Members of Parliament, then the Foreign Office has more than the obvious reason to be sure that it offers help and not obstruction in the committee's future investigations.

But what about the organization of the nuclear energy industry in Britain? This is the nub of what the committee has to say. This is where it is divided among itself. This is where the report is least convincing. Briefly (see page 854) the committee wishes to create a single "commercial organization" to undertake the design and construction of the "nuclear boilers" in future nuclear power stations. By this proposal, the committee echoes the suggestion of the Atomic Energy Authority, which put forward in evidence a scheme in which the authority itself would join with interested companies in a commercial venture to

manufacture the essential parts of nuclear power stations. The committee and the authority agree that it would be necessary for the design and development facilities of the authority to be transferred to the new company. The committee goes further than the authority by taking the line that the authority should be dismembered into parts with separate functions. Although Lord Penney himself acknowledged that a "radical reconstruction" of the authority is necessary, he does not seem explicitly to have advocated such a drastic step.

Because the committee has been bold and because its principal conclusion smacks a little of a tidy paper scheme intended to get rid of "duplication" or some other illusory economic defect, it will be tempting to assume that it has been entirely naive. It is therefore only proper to acknowledge that some of the most obvious pitfalls have been spotted and that suggestions have been put forward for not falling into them. In its defence against the charge that a single design and manufacturing organization would necessarily acquire monopoly powers—one of the points made by the Central Electricity Generating Board—the committee replies that one essential feature of the scheme should be that the electricity boards are empowered to consider tenders from outside the United Kingdom. By the same test, the argument goes, the new organization would have to be prepared to lose—or at least to risk-quite large amounts of money in its own commercial dealings in the export market—a radical notion for the use of public funds. The difficulty is, of course, that these theoretical safeguards may not in practice be safeguards in any real sense. It is hard, for example, to see a government which is consistently reluctant to let the nationalized airlines buy aircraft overseas acquiescing permanently in a scheme that would allow other nationalized industries to spend very much larger sums of money on capital equipment from abroad. At the same time it is hard to see the British Government being prepared to relax its interest in the uses to which substantial sums of public money have been put. In other words, the scheme which the select committee and the Atomic Energy Authority have between them hatched is somewhat idealistic, to say the best of it.

But does it follow that every idealistic proposal is nonsense? That would surely be an unreasonably cynical view. But the difficulty which the committee should have faced much more squarely is that, in the advocacy of idealistic notions, it is essential to make a closely argued case. In particular, it is necessary to answer detailed questions such as the precise meaning of the word "commercial". Would the proposed nuclear boiler company be able to move into the manufacture of computers if it considered there were better profits to be made in that direction, for example? Would it be compelled by its constitution to accept all intending participants as shareholders, and, if not, how could the granting of this franchise be squared with the Monopolies Act? How would the supposed boiler company respond to technical change? Would it, for example agree to disband itself if, at some time in the future, the electricity boards could easily order the components of "nuclear boilers" separately? To ask all these questions does not imply that none of them can be answered. The committee itself, or perhaps Lord Penney or his successor, may have perfeetly acceptable answers. But the proposal in its present form is altogether too imprecise. Among those who think of it as a bogy, for example, will be some who regard it as a cloak for nationalization and others-Lord Penney, perhaps?-who see it as a means by which the essence of the Atomic Energy Authority might continue to exist a little more remotely from the pressure of detailed scrutiny by the Government. And, above all, there is bound to be a nasty suspicion that the scheme might not work for some unsuspected reason. What this implies is that the select committee should either have done a more detailed study of these points or should, alternatively, have put forward the proposals much more tentatively.

There is, too, always a doubt whether any reorganization scheme which does not command a fair degree of political agreement has any chance of success. This is not to argue that select committees and ministers should never set in train radical or provocative schemes. but merely to point out that in matters like these. political truths are just as significant as commercial ones. From the attitude of Conservative members of the committee, it is fair to assume that any Conservative government in Britain would oppose the establishment of a monopoly supplier. But it would be unlikely to unscramble an organization which was already working efficiently, particularly if it had achieved some measure of export success. Any move towards the central design authority, if it is to be permanent. should therefore be made with all speed, for Mr Benn cannot be unaware that there will be an election in 1971. If the industry is still in the process of reorganization then, a Conservative promise to return it to private hands is likely to prove an irresistible tempta-Quite apart from the merits of the case, this would not be a way of ensuring success for the industry -rather the contrary. And because of the outstanding contracts, the last of which is to be finished in 1973, rapid change may be the last thing the industry is willing to contemplate.

These are the points on which the committee is vulnerable to criticism. A close reading of the report will show that the committee has worked hard, and covered as much ground as could reasonably be expected of it. If in the future it is given technical assistance on the right scale, it could become a power in the land. But as things are, it has skimped on thinking, with the result that the document is much less persuasive than it could have been. From this it does not follow that the select committees are ineffectual, but rather that they need even more help and encouragement than they have had so far. This particular committee will need all the help it can get when it comes to enquire into defence research establishments in the weeks ahead

There remains the question of what the Minister of Technology should do about the Atomic Energy Authority. Simple men will hope that he will now be emboldened to do at least those simple things which stare him in the face. For one thing, he should relinquish responsibility for thermonuclear fusion, which should now be with the Science Research Council on an elastic budget and not short commons by ministerial decree. The weapons laboratory at Aldermaston should be transferred from the AEA to one of the ministries, possibly the Ministry of Defence. problem of what to do with Harwell is daunting by comparison, but there is a case for considering novel -solutions such as the creation of several autonomous laboratories, with separate sources of finance, in one physical environment. The trading functions of the AEA, including the sale of fuel elements and of isotopes for research, could be separated into one commercially conducted nationalized industry, but this is hardly an urgent matter. The central need is to decide just what part will be played in the future development of nuclear energy by the men now engaged on design and development for the AEA. The solution which the select committee has proposed is only one of many. Another, for example, is that the AEA might be divided between the electricity boards and the industrial companies. For even though the select committee is probably right in saying that there is no pros--pect of anything approaching competition in the present -circumstances in which three commercial enterprises compete for what little business there is to be had, and although everybody will agree that the companies should be more closely concerned with design and development, it is by no means obvious how this should best be done. Plainly the Minister of Technology will have to start where the select committee left off. He had better make haste.

Japanese Science Policy

Science in Japan comes under scrutiny in a recent study by the Organization for Economic Cooperation and Development (OECD, £1 10s.). This is the seventh review of national science policy which the OECD has published; the others cover Sweden, Greece, Belgium, France, Germany and the United Kingdom. The review concludes that Japan suffers from an unwieldy advisory structure and a multiplication of laboratories too small to justify themselves. Advice is supplied by two principal organizations—the Council for Science and Technology, and the Science Council of Japan. The first of these, the report says, is too concerned with government affairs, while the second, whose relations with the government have for several years been in a permanent state of crisis, is too involved with academics. There are in addition four specialist advisory agencies, covering atomic energy, radiation, marine science and space.

Much of the direct administration of science in Japan is carried out by the Science and Technology Agency. The position of the agency is complicated, the report says, because it also acts as secretariat for the Council for Science and Technology and the four specialist

agencies. Sometimes it is in the position of being both judge and advocate. Research conducted by other government ministries "presents a picture of extraordinary dispersal of effort". Often the effort is too small to meet the threshold requirements for concerted programmes of research. There is further danger, the report suggests, in the sharp division between funds for university research and for other research. This division represents a major obstacle in the development of coherent science policy.

Despite the success of Japanese industry since the War, the report suggests that there is still an overheavy reliance on imported technology. "There is still some way to go before Japanese technological innovation commands respect from those nations whose technology has been the basis for Japanese development." If Japan really does want more technological independence, it will have to pay more for it, by stimulating domestic innovation. The recent establishment of a Research Development Corporation to underwrite high-risk and development projects could help, the report concludes.

Japanese witnesses to the review body gave interesting details of a project intended to collect together a large number of the government's research institutes in a research park at Mount Tsukuba. The plan sounds ambitious: the park will have several universities and some forty government institutions, as well as some private ones. The park will be some 50 kilometres from Tokyo, and an express highway will be built between the two. At the moment land is being obtained, and construction will begin next year—within ten years the park should be complete. The park will include a great variety of institutions, including pure science, architecture, mechanical engineering, disaster prevention, medicine and agriculture.

Fewer Claims on Oxford

by our Oxford Correspondent

APPLICATIONS for admission to Oxford University fell by 8.5 per cent this year. It is, of course, too early to say whether this was caused by a loss of interest in the older universities among sixth formers, or indeed whether the decrease is significant at all. There may not have been any change in the quality of candidates—examination scripts are only being marked now—so that the fall in numbers may merely result from stiffer pre-selection of candidates by the schools.

But, in any case, long before the fall in the number of applicants became known, the university decided to increase its contacts with the schools so as to encourage sixth formers to apply to Oxford. At large and well equipped schools, such as Manchester Grammar School, which sends 70 to 80 boys on to university each year, Oxford, with its college system and academic and administrative idiosyncrasies, is very much a known quantity. Such schools need no proselytes; candidates from them are many and well informed. But at smaller schools, where a tradition of entrance to universities has not been established, Oxford may be regarded with a certain amount of awe, a distant and perhaps unsympathetic institution, little interested in applicants from unknown schools. One head master, for example, has commented on the fact that some Oxford women's colleges used not to make past examination papers

All Change on Aldabra

The Under-Secretary of State for Defence for the Royal Air Force (Mr Merlyn Rees): "... I want to make it abundantly clear at the outset—and this to a very large degree limits my remarks this evening—that no decision has yet been made whether or not to use the island of Aldabra for defence purposes. As my right hon, friend the Secretary of State for Defence assured the House on 5th July, the scientific issues at stake will be taken carefully into account in reaching any decision." Hansard, Col 1845, October 25, 1967.

The Prime Minister (Mr Harold Wilson): "... In overseas terms, we have decided not to proceed with the Aldabra project—(Interruption)—the establishment of a staging post in the British Indian Ocean territory. As far as we can at present estimate, it should mean that expenditure next year will cut defence spending to the level which last July, with great difficulty, we had scheduled for 1970–71. It is an advance from 1970–71 to 1968–69—I think a remarkable achievement." Hansard, Col 1341, November 22, 1967.

available to applicants, so that only schools which regularly sent in entrants could collect papers for the aid of future candidates. (This anomaly has now been cleared away. From this year onwards the Colleges Admissions Office will deal with women's applications as well as men's.) Relations between schools such as these and the newer universities have been much stronger: Leeds University has been particularly active in sending members of its staff to talk to sixth formers. At the University of East Anglia, a report on a student's work in his first year is sent back to his school, and Sussex University gives an account to the school of how its candidates fare at the entrance interview.

This is not to say that Oxford has been entirely idle, for more and more candidates have been coming from state schools in recent years. But recruitment has largely been left to individual colleges. Last summer, the Colleges Admissions Office began arranging with a number of schools that Oxford dons should come and talk to sixth formers or staff about any problems there might be in applying to Oxford. It is hoped that the first visits may be made next term so that it might be possible to gauge the success of the scheme by the entrance figures for next year.

More Big Spending

Britain should go ahead and support the plan to build the CERN 300 GeV machine, according to Professor P. M. S. Blackett, President of the Royal Society. In his presidential address at the anniversary meeting of the society on November 30, Professor Blackett said that the big machine would provide a natural follow-up to the "brilliantly successful" 28 GeV machine at Geneva. There was wide agreement on scientific grounds that the machine should be built, he said, but doubt had arisen because of its great cost. "Some scientists fear that the fifteen years or so forward commitment which such a big project requires could put at risk the provision of adequate finance for the great bulk of little science, which cannot be planned far ahead. After careful thought on all these matters, I am convinced that Britain should decide to join in this great and exciting European venture—and the sooner the better."

Professor Blackett went on to suggest that in reality there was no real conflict between big and little science. Of course, it was possible that the demands of big science would starve little science of funds, but in Britain this had not happened. The big spenders—nuclear physicists, high energy physicists, space scientists and radio astronomers—had beaten a path to the Treasury door and made it easy for little science to follow. "In short, the big sciences have raised the scale of expenditure on research to a new level, and this has carried little science in its wake."

Professor Blackett spoke with great enthusiasm about the increased level of exchanges within Europe, and the new arrangements for which the Royal Society is acting as a clearing house. And, in spite of the other demands on national resources, Professor Blackett said he was convinced that the rate of growth of the science budget should remain high for a long time yet. This called for very careful selection of projects for support, and some scientists were bound to feel frustrated—the biggest protests, he said, were likely to come from those who had been best fed in the past. A close comparison with manufacturing industry could be made-many firms work very hard to make their tenders for a given contract. But only one firm wins it. So it must be with British scientists, Professor Blackett concluded.

Royal Society Blooming

The move to new premises seems to have left the Royal Society in a cheerful frame of mind even if the appeal for funds to pay for the capital cost of conversion is still some £200,000 short of the target of £850,000. In practice the programme of exchanges with European countries seems to have captured a good deal of the society's enthusiasm. The society describes its operations in the year past as "a very successful start to a new programme". There seems every prospect that the work of the past year will be increased in the months ahead and that European countries will come forward with proposals for spending money which will allow the Royal Society to draw more heavily on the British Government in support of the programme of exchanges. In the year ahead, £50,000 has been made available by the Government for this work.

Government spending through the society is increasing steadily. In the year to last April, a total of £564,000 was spent in this way, roughly a quarter of it on the support of scientific research. The society spends roughly the same amount of government money—£146,300—on participation in international ventures, mostly through the International Council of Scientific Unions.

The government contribution in the current financial year will amount to £657,000 and will include for the first time a contribution towards the Naples Zoological Station. It had been agreed before devaluation that the Royal Society will be the vehicle for the British Government contribution of £28,000 a year (50 million lire) towards the station so as to qualify for a seat on the administrative council of the station. Presumably the cost will now be higher.

Among the new ventures undertaken by the fellows of the Royal Society in the year past is the setting up of a study group on modern population, chiefly as a result of a discussion held at the society on May 17 this year. The chairman of the study group is Dr H. A. Cole.

Big Biology

Consideration of the philosophical bases of the International Biological Programme (IBP) has so preoccupied scientific leadership in the United States that observers elsewhere have wondered when American biologists might actually get down to specific projects, and what these might be. A stream of stately essays has been the main output so far; yet Phase 2, or the operational part of the IBP, was supposed to start last July. At that time, however, the National Committee was in the midst of Congressional hearings on IBP and its funding.

It now seems that, having scrutinized the underlying concepts of IBP more thoroughly than any other community, the United States may now undertake work that is proportionately more significant. This is clear from the most recent report of the National Committee, Report No. 3, Part 1, now published. Of the greatest interest are the major integrated research projects specially developed within IBP guidelines by the National Committee and directly sponsored by it. The radical sweep of some of these programmes makes most of the efforts of other countries look very small beer. None is expected to cost less than \$2 million and several will cost a great deal more.

Six such integrated programmes have already been adopted by the US National Committee and were discussed in detail in the committee's report to the House of Representatives Subcommittee on Science, Research and Development. These are: (1) an aerobiology programme to study on a world-wide scale the dispersal of airborne bio-material such as pollen, spores, algae, pathogens, and insects, to make the prediction of crop diseases and other pests more reliable and control more effective (cost \$16 m); (2) large ecosystems analysis of which six contrasted regions have been chosen including a polar environment and a South American tropical forest (cost \$45 m); (3) a joint Canadian study of Eskimo populations based on at least three widely separated population centres in Alaska, Arctic Canada and Greenland whose communities all stem from the same origin but which have become differentially adapted (cost \$2 m); (4) intensive work on the Hawaiian "evolutionary explosion" while it remains identifiable—this rich flora and fauna has all evolved from 700 immigrant ancestors in the few million years that the islands have been isolated. but the area has already lost more land species than the whole North American continent put together through the accelerated impact of man (cost \$2 m); (5) phenology within the United States, or the impact of climate and seasons on animals and plants, is expected to lead to a series of maps of the country in terms of nest-building, fish-spawning, bud development, seed production, useful for biological prediction (cost \$2 m); (6) ecology of migrant populations, primarily concerned with the effects of urbanization on rural peoples and particularly those migrating from rural southern states to large city receiving areas such as Chicago (cost \$10 m). All these programmes now have a research director and some sort of headquarters, although none have yet secured funds. The committee shows confidence that they will be obtained, and hopes for House sympathy over requests.

In addition, nine other major research operations are under review and a whole series of high-level "workshop" meetings are taking place this month and next to bring these to a head. They cover the adaptation of peoples to high altitudes; experimental biogeography of the sea; control of insects by plants and plants by other plants; biological control of pests, insects and other organisms; (in conjunction with Japan) adaptive processes in hybrid human populations; adaptability of primitive peoples; convergent and divergent evolution, and the physiology of colonizing species; plant gene pools; nutrition and new foods.

Apart from these committee-sponsored moves in a grand strategy, the recent report lists over 100 individually proposed schemes relevant to the IBP, many of which are going on anyway and are already financially secure. The number has now risen to a total of about 170. This section of the report is quite a rag-bag, and the items very uneven in value and interest. This section much more resembles the national programmes of other countries such as Britain where the impression is left that the IBP has provided a new system for indexing research projects already in progress.

Some of the written answers to the Congressional Sub-committee's enquiries are revealing. consider what effect a lack of funds would have on the international programme as a whole and on American scientific prestige and US standing generally, the witnesses answered: "The IBP National Committee feels that this would not greatly affect the prestige of American science. At the same time, it points out that experience in the last 15 years has demonstrated that, if any international scientific programme is to be successful, the US must take a strong and vigorous role. It applies the analogy of 'critical mass'; with added fuel the programme will 'go'; with decreased fuel the programme will falter . . ." Summing up the committee evidence: "Inadequate US support would adversely affect this international research programme. Inadequate US support and participation would delay urgently needed worldwide ecosystem research.'

Anniversary in Chicago

The twenty-fifth anniversary of the first controlled release of nuclear energy rolls around this week. The University of Chicago is holding two days of ceremonies to celebrate the birth of the nuclear age in a squash court under its football stadium on December 2, 1942. The stands at Stagg Field have now been demolished, and five of the fifty who witnessed the scene are now

dead, including the team's leader Enrico Fermi, Arthur H. Compton and Leo Szilard. Among those to be honoured by the university this week will be Robert Duffield, director of the Argonne National Laboratory.

The enthusiasts for commercial exploitation of the nuclear reaction have, in the United States at least, further cause for celebration. This year marks the tenth anniversary of the first sale of electricity generated by a nuclear power station. (The Schippingport reactor in Pennsylvania, with a new core, is still serving Pittsburgh today.) The boom in orders for new power plants is continuing; twenty-six were made known in the first three-quarters of this year compared with twenty-three in the corresponding period last year. And the contract has just been signed for southern California's combined nuclear power and desalination plant, expected to be not only the world's biggest, but one of the cheapest in terms of the delivered cost of its desalted water.

Moreover, next week should see the first nuclear explosion sponsored jointly by the Atomic Energy Commission and private industry to test the peaceful (that is, commercial) possibilities of such explosives. Project Gasbuggy, as someone has thought fit to label it, will consist of a 26 kiloton explosion 4,000 ft. down in the sandstone formations near Farmington, New The AEC and the El Paso Natural Gas Company want to see whether the blast can release the gas locked up in an otherwise unprofitable gas field. The AEC has at least six other commercial experiments scheduled—one to get at oil, another at copper. Conceivably some day the commission could be in such heavy demand as a blaster that it might have to contract out the business of setting off nuclear explosions to a private company.

Discovery of X-rays

On November 8, 1895, W. C. Röntgen, professor of physics at Wurtzburg University, observed a phenomenon which led to his discovery of X-rays. Almost immediately after the discovery, applications blossomed at a remarkable rate, and some fell even within the ambit of the original discovery itself. Even today, when the importance of the rapid application of new ideas is widely appreciated, this rate of application is rarely if ever equalled. Dr D. Chilton of the Science Museum discussed the reasons for the rapid application of Röntgen's discovery in a paper to the history of science discussion group at the Royal Institution on November 15.

One reason for Röntgen's success seems to have been the remarkable speed at which he worked. Dr Chilton quoted from a speech by Professor Ewald—"Röntgen was a character who hated to part with an unfinished experiment by publishing it. He made the chance observation on November 8 and, working feverishly in the next six weeks, found nearly all the properties of X-rays which were to be known within the next ten years . . . Physicists and medicals alike tried to find out more about the properties of these rays than Röntgen had indicated in his ten-page pamphlet which he sent out to his friends as a New Year's gift." The reaction was certainly remarkable; Dr Chilton said that by the end of April 1896, there had been sixty-one references to X-rays in the pages of Nature, an average

of three to four each week. By February 1, the Lancet was reporting that the invention was so far advanced that in Belgium it was being brought into practical use in the hospitals. This was just one month and three days after the first announcement of the dis-

Other applications were also quickly realized, Dr Chilton said. Röntgen himself noted the way in which X-rays showed up lack of homogeneity in a metal structure, now the basis for industrial testing of metals. S. P. Thompson showed that gem stones and their glass imitations differ in their absorption of X-rays. All this, Dr Chilton said, was derived almost directly

from Röntgen's first paper.

Röntgen's "chance observation" came when he was working on electric discharges within an evacuated Working in a darkened room with the glass tube. tube enclosed in black paper, he noticed that a film of barium platinocyanide, a well-known fluorescent material, showed a bright fluorescence whenever the tube was operating nearby. But if the discovery was a piece of luck, from then on Röntgen left nothing to chance.

New Building at Teddington

MR ROBERT MELLISH, Minister of Public Building and Works, cut the traditional sod on November 28 to mark the site of a new laboratory building at the Ministry of Technology's National Physical Laboratory at Teddington.

The laboratory, which will be known as Petayel Building after Sir Joseph Petavel, a former director of the NPL, should cost about £650,000. The NPL is already the third largest research establishment in Britain and the new three storey building will provide an extra 34,000 sq. ft. of laboratory space and 21,000 sq. ft. for offices. The main building will consist of a central reinforced concrete core containing the main staircase, lift and common services. Surrounding this will be the laboratories which, on each floor, will be divided into seven zones, each sub-divided into areas by low partitions. Although the laboratories will be without windows, thereby permitting an economical design for the engineering services, the artificial lighting and air conditioning will, however, provide a stable environment for research. The offices will be located on the perimeter of the building and will have natural light and ventilation.

Petavel Building, which should be completed by September 1969, is a departure from the normal type of research building. It has been essentially designed to meet the changing needs in research; as Mr Mellish put it, "Petavel Building is, we believe, a good answer to the request for a general purpose laboratory which would provide the conditions required for a wide range of the National Physical Laboratory's work and which would also be capable of modification to provide other conditions with a minimum of expense". The contractors began work on November 29, and it looks as if the ministry is determined to have the building finished on time.

Protein from Petroleum

Interesting results have been obtained from experiments in which yeast cells have been used to produce protein concentrate from petroleum hydrocarbons. The pioneer work in this field was done at Lavera, France, and for the last five years the Shell BP group has been engaged in a research and industrial programme aimed at protein production on an industrial scale, chiefly at Grangemouth, Scotland.

Protein concentrates can be made by two processes: the product is an off-white, free flowing, tasteless powder which has a relatively high lysine content but which is low in methionine. One process starts with refined petroleum hydrocarbons and the other with gas or diesel oil. These unusual substrates are fermented by yeast cells grown in conditions of favourable pH and temperature and provided with adequate substrate and minerals. The fermented product is centrifuged and treated to produce a cream suitable for the drying From each ton of hydrocarbon, a ton of protein concentrate is produced. This is suitable for use in animal foodstuffs and will possibly compete in food value and cost with more familiar protein concentrates such as fish meal and soya. Laboratory and early field-scale testing of the nutritional value of the product is being supplemented by toxicological studies using albino rats. Stringent safeguards have to be satisfied before the protein can be used for human consumption, but it has been suggested that it could be included in bread and biscuits. Furthermore, the protein can be extracted and coagulated to form a material with a structure resembling meat such as veal or chicken.

These results are shortly to be published in detail in the *Journal of General Petroleum*.

A Ship from the Bottom

The raising and restoration of the seventeenth century Swedish warship the Wasa is a strikingly brilliant piece of marine archaeology, and the small but informative Wasa Exhibition at the Science Museum in London does it justice. The exhibition, organized by the Wasa Museum and the Swedish National Maritime Museum under the auspices of the Swedish Institute, traces the history of the ship from its construction and sinking on its maiden voyage in 1628 to the location of the hull in 1956 and its recovery in 1961.

The Wasa, for some unknown reason, capsized and sank before it had left Stockholm harbour. Most of the heavy cannons were recovered in the seventeenth century by divers using the most primitive of diving bells and the ship was then forgotten. In 1956, however, it was relocated at a depth of 100 feet, completely silted up with mud, and the Swedish Government decided to raise it. This posed enormous technical difficulties which have been brilliantly overcome. The exhibition shows with models and photographs how the hull was lifted in seventeen stages until it was at a depth of 60 feet and finally raised to the surface in April 1961.

Once on the surface, 1,000 cubic metres of mud was removed and sifted, yielding about 24,000 objects including clothing (see illustration), food, coins, sails and utensils. From these an authentic picture of life aboard a seventeenth century warship can be reconstructed. The woodwork of the hull was remarkably well preserved as several photographs and replicas show. Fortunately, the salinity in the Baltic is too low for wood boring animals such as Teredo and this

more than anything else accounts for the good state of the woodwork.

Preservation of the hull is an enormous task which is still going on. It is the largest water-logged object ever to be preserved and the Swedish authorities are sparing neither time nor expense to make sure it is done properly. To prevent the wood from shrinking as it dries out it is being impregnated with polyethylene glycol. All the movable parts are being stewed in a 60 per cent solution at 60° C and then carefully dried. The main bulk of the hull—190 feet long—is being continuously sprayed with polyethylene glycol solution and this operation will not be completed until 1971. It will then be dried out under carefully controlled humidity and eventually all the pieces reassembled.

The seaman's clothing on this model was recovered from the hull of the Wasa. (Science Museum photograph.)

The exhibition, which whets the appetite for the real thing, will stay in England until 1969 during which time it will be shown at most provincial museums. Similar exhibitions are touring North America, Australasia and the continent of Europe.

Irradiating Food

Some estimates indicate that as much as 20 per cent of the world food supply is wasted by spoilage—in some areas this figure may reach 50 per cent. Clearly any technique for reducing this waste would be welcome, which explains the considerable interest in food preservation by irradiation. One investigation of this sort is being carried out under an agreement between the Austrian Atomic Energy Agency, the European Nuclear Energy Agency and the International Atomic Energy Agency. The work is done at the Reactor Centre at Seibersdorf in Austria, and the project has just published details of progress up to the end of 1966.

The report shows that the project has been slow to get off the ground. In 1960, the ENEA set up a committee to examine the feasibility of the process; in 1961 Austria indicated willingness to do the experimental work, on fruit and fruit juices. In 1962 the draft programme was drawn up; in 1963 a draft agreement was submitted, and it was finally signed in September 1964. Work began in January 1965, but the irradiation facility was not finished until September this year. Initially work will be concentrated on fruit juices, both because of their convenience and because the yeasts which are mainly responsible for the spoilage of fruit juice are a well studied group of micro-organisms. The experimental work is divided into three main fields: radiosensitization studies on yeasts and moulds, technological studies including radiation chemistry and wholesomeness tests.

Like other methods of food preservation—smoking, drying, canning or freezing-irradiation affects the taste of the food. Results at Seibersdorf with grape juice have not yet established which compound is responsible for irradiation taste, but the indications are that the undesirable taste is not caused by protein degradation. Some evidence indicates that flavour changes can be minimized by irradiation at very high dose rates, and preliminary results from work in Switzerland with an accelerator indicate that apple juice can tolerate a high dose rate without significant flavour change. Of rather more importance is the work necessary to establish that the new process is safe for human consumption over long periods. At Seibersdorf animal feeding trials are being made with three types of animals—rats, mice and miniature pigs.

Work with apple juice has established that only one compound, furan or a furan derivative, was specifically produced by the irradiation process. But compounds already present in the unirradiated juice, like acetaldehyde, may be increased. The concentration of acetaldehyde continues to increase during storage, while cupronaldehyde, present after irradiation, appears to decline in concentration during storage. The irradiated apple juice, the report says, could be stored successfully at room temperature for 200 days.

Architects and Engineers

THE building industry has for a long time been troubled by differences that exist between the members of the various professions that work together in a building team. Architects and engineers have tended to become isolated from one another because of differences in their professional training. An attempt is now being made to find ways of breaking down the barriers between them, so that the skills and total knowledge of individuals can be used more effectively than at present. A joint education group was set up in 1966 by the Council of Engineering Institutions (CEI) and the Royal Institute of British Architects (RIBA) to find ways of improving the understanding during training between the disciplines of architecture and engineering, and to consider the possibility of training people to be both engineers and architects. The nine-strong group of two architects, four engineers and three RIBA staff has just produced its interim report, which covers the first of these problems and gives a preliminary statement of the second.

Much of the present lack of communication between

architects and engineers is caused by differences in the educational systems. Both professions require at least six years' training, but the academic content varies. Engineers take a three-year academic course followed by three years' practical training, while architects have a year of practical training after their third year, in the middle of their academic course, so that theory and practice are interwoven. But the most fundamental difference is in the approaches of the professions. Engineers are given highly technical training with little concern for the human side of the problems. Architects, on the other hand, consider the human factor to be of prime importance, but are sometimes short on technical expertise. Some subjects that are common to both disciplines have up to now been treated differently. In structures, for example, architects are concerned with strategy, and engineers with tactics. This means that architects study the causes and effects of certain choices, while engineers are there to see that the choice which is finally made stays up. Despite his greater technical knowledge, the engineer must leave design to the architect.

The problems of communication are not new, but The CEI, which there are now signs of progress. represents the majority of the engineering institutions, is aiming to provide a common theoretical basis for all engineers which can then be applied to any specialist field. This approach does not encourage integration with architecture, but the fact that the CEI is involved on the education project indicates its awareness of the situation. The Council for National Academic Awards, which awards degrees to students at polytechnics, has the power to accept or reject courses into the degree category. It therefore has considerable influence on the content of non-university courses. The group has several suggestions to make for increasing understanding and co-operation, based on the idea of students working together. Project work could be carried out by architecture and engineering students together, and some parts of the syllabus could be shared. The group believes that "orientation" courses for engineers entering the building field are worth investigating. Teachers from one discipline who appreciate the problems of the other could also help. The ultimate solution as described by the group rests on the establishment of educational institutions where architects and building engineers can work together. This would require engineers to commit themselves to the building field at an early stage—to good purpose, the group thinks.

Free Enterprise under the Sea

AMIDST all the rumours of new Government support for oceanography in Britain, it is refreshing to find some young men who are prepared to back their hunches and build for the future under the sea without waiting for the cat to jump.

At Lintott Engineering Ltd's Horsham works last week, Britain's first mobile submersible was given its first demonstration. Called SURV, for Standard Underwater Research Vessel, it was initially the concept and design of M. J. Borrow, R. E. Lloyd and J. M. Metcalf of Underwater and Marine Operations Ltd (Woking), who have seen it through to the fully engineered prototype constructed by Lintott and demonstrated last week after two months of sea trials.

It is intended as a broad purpose underwater tool for the engineer and research worker at continental shelf depths, and carries two men. The makers claim that its performance "covers all aspects of undersea work including bottom surveys of sea-bed conditions before, during, and after laying of oil and gas pipelines and submarine cables". They also see applications for geology, marine biology, fish farming, surveillance, and as a search and recovery vehicle. There are provisions for outside manipulations and coring. (It might well have come in handy as an aid in the hazardous operation to recover the Royal Navy Buccaneer that plunged into 300 ft. of water off the Lizard a couple of years ago.)

To do all this, a cylindrical pressure vessel of 51 ft. diameter with 11 in. thick mild steel walls has been chosen. This has a theoretical collapse depth of 3,500 ft. The pressure hull is enclosed in a glass fibre shell to make SURV as rugged to surface treatment as a glass fibre boat. The prototype has been rated for 260 p.s.i., equivalent to 600 ft. depth, and is expected to be progressively reclassified down to 1,000 ft. which lies within its design safety factor. The crew environment is "near normal", that is, they breathe air at atmospheric pressure, and submerged endurance is 36 h which in an emergency could be extended to 48 h if the crew sit still. Arrangements for neutral buoyancy and two independently rotatable motors mounted on each side give the craft exceptional manoeuvrability. It can move forward and backward, turn and keep station at a given depth—in addition of course to vertical manoeuvres-all of which was convincingly demonstrated in the Lintott tank last week. It is not exactly nippy, however. Maximum speed is 2½ knots submerged or at the surface. For surveying this is still a considerable gain on the free diver's performance. In air, SURV weighs 6.1 tons excluding crew, not likely to impose much strain on harbour facilities or support ships and so qualifying it for operations in almost any dart of the world, the sponsors hope.

The cost of preparing the first SURV for operations is understood to be about £60,000—roughly 50 per cent of the cost of similar American submersibles, of which General Dynamics' vehicle is the nearest in design. At present SURV's sponsors look to hire rather than outright purchase to recoup their outlay. Hire price, which includes their own "driver", is negotiable but likely to fall within the range £300–£400 per day. So far, they have enquiries but no firm offers. The presence of two members of the National Institute for Oceanography at the demonstration was considered encouraging.

World Health

Within the past few years there has been unhappy evidence that some diseases, far from declining as public health standards improve, are actually increasing. Cholera El Tor, plague, yellow fever, trypanosomiasis, ancylosomiasis, viral hepatitis and venereal disease have all increased, according to the third report on world health, compiled by the World Health Organization (WHO, Geneva, £1 15s.). Against this must be set some real achievements—tuberculosis, for example, which killed one person in nine in the United Kingdom at the turn of the century, caused only one death in 180 between 1960 and 1964. But there is a great

discrepancy between the achievements of the developed countries and those of the underdeveloped world. Europe has been free of cholera since 1923, but during the past ten years it has flared up again in India and Africa. Until 1960 there was a decline, from 212,000 cases in 1950 to 33,000 in 1960, but since then the disease has come back strongly, with a total of 94,000 cases in 1964; the worst hit countries are India and the Philippines.

There is clearly no room for complacency when diseases can re-establish themselves as strongly as But the underlying trend is more hopeful; infant mortality rates, always a good indicator of public health standards, show improvements almost everywhere. In some cases the improvement is dramatic, with mortality rates down by 50 per cent or more. Other countries show smaller improvements, in some cases because mortality rates for babies were already low, but many developed countries which have achieved low rates have reduced them even further. Zealand shows a reduction in infant mortality of 18.7 per cent since 1954, and Canada a reduction of 17.6 per cent. Crude death rates also show a reduction in recent years, with some interesting exceptions. The United States, Argentina and Cuba all show increases of death rate since 1954, and in Europe death rates have tended to remain much the same over the past decade. Elsewhere, decreases have been common.

In developed countries, cardiovascular diseases account for about 40 per cent of all deaths. High blood pressure, the report reveals, is almost universal; only a few very primitive populations and populations living at high altitude are free from it. Cancers of the respiratory system have also become a serious health hazard; in the UK deaths from cancers of this type have increased by 69 per cent since 1954. But there are some striking variations between countries which might be expected to be similar; in Finland the death rate per 100,000 for respiratory cancers was 58·1 in 1963, while in Norway the figure was only 18·7.

Accidents, while not strictly a health problem, are becoming more and more important as a cause of death. In the age group from 1 to 35, they now rank as the leading cause of death. In developing countries, accidents are less significant, but they are beginning to increase in importance, and sometimes rank as the sixth or seventh commonest cause of death.

Response to Aldabra

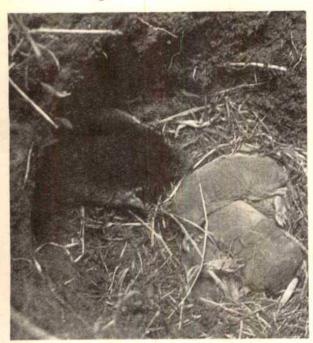

Those who have been campaigning, in the weeks past, to dissuade the British Government from using the island of Aldabra as an air staging post seem now to be entirely willing to press for the facilities that will be needed if the island ecosystem is to be properly studied. It seems, however, to be agreed that the first step should be a clarification of the political status of the island. Administratively, the island comes under the umbrella of the British Indian Ocean Territory, which was originally created for defence purposes. Obviously the British Government could do much to reassure the ecologists by formally detaching Aldabra from that organization.

As yet there is no plan for the long-term conservation of Aldabra, but the Royal Society is eager to help in preparing one. The Nature Conservancy is also a

natural participant in this work, but there would have to be an extension of its terms of reference to allow the conservancy to operate outside the United Kingdom. An official of the Royal Society offers the Charles Darwin Foundation Research Station on the Galapagos Islands as a model for what might be done on Aldabra. It seems to be understood that the Smithsonian Institution, urged on by the National Academy of Sciences in the United States, will be a willing partner in this part of the operation. Two of the nine members of the Royal Society's expedition to Aldabra this summer were from the Smithsonian Institution.

The international research station is a long-term objective, however. The expedition now returned from Aldabra was also impressed with the need for more urgent steps to be taken. One problem is to prevent the fishing of the waters around the island. At present the arrangement is that a Seychellian has been licensed to fish off Aldabra, with the result that there is a danger of the green turtles becoming extinct. Dr D. R. Stoddart of the University of Cambridge, who has just returned from the island, says that the way in which the fishermen live on the island temporarily may be almost as great a danger. In the year ahead, the Royal Society plans to send another expedition to Aldabra in January, and one member of the party of twenty—Mr M. J. Penny, an ornithologist—will probably stay there until March 1969. Everybody hopes that plans for the permanent conservation of the island will by then be complete.

Moles Underground

This picture, the first ever taken of moles underground, won the Wildlife Cameraman of 1967 competition organized by the Council for Nature and Wildlife and the Countryside magazine. The picture, taken by Mr Peter Stafford, shows a parent mole entering its nesting chamber three feet beneath a field in Sussex. The young are lying in a nest of dead grass, with at least two tunnels leaving the chamber. The feeding habits and activity of moles were described by Kenneth Mellanby in Nature (215, 1128; 1967).

Parliament in Britain

Foot and Mouth Disease

MR P. GORDON WALKER stated that research on foot and mouth disease was concentrated at the Animal Virus Research Institute, Pirbright, where it made up about three-quarters of the work of the institute. Grants from the Agricultural Research Council to the institute during the last five financial years had been as follows: 1962–63, £536,587; 1963–64, £248,863; 1964–65, £390,462; 1965–66, £499,379; 1966–67, £522,521. Net expenditure, and hence the size of grant needed, varied with the revenue from the sale of vaccines overseas, which in turn depended on outbreaks of the disease overseas. (Written answer, November 20.)

Dounreav

Two employees have left the Dounreay Experimental Reactor Establishment to go to the United States during the last six months. Mr A. Wedgwood Benn, giving the figures, stated that one was a senior machine operator accompanying her American husband on his return home. The other was a scientific officer who mentioned better pay as his main reason for leaving. (Written answer, November 21.)

Seals

THE Minister of Agriculture, Fisheries and Food, Mr F. Peart, announced that as the National Trust was unable, on the basis of its existing information, to agree to continue culling seals on the Farne Islands, the Natural Environment Research Council suggested that it would be desirable to have a review of the scientific facts and their interpretation by a wide range of scientific opinion. The council was arranging a meeting of scientists as soon as possible. (Oral answer, November 21.)

Defence

MR DENIS HEALEY came in for some vigorous criticism when he announced full details of the defence cuts which the British Government has made as part of the devaluation package. The word betrayal was mentioned by at least one member, but others thought Mr Healey had not done enough. What he has done is bring forward the date for the withdrawal of the aircraft carrier Victorious, saving £4 million, cancelled 8 Buccaneer aircraft, saving £6 million, deferred some Army equipment and cancelled an order for helicopters from the United States, saving another £11 million. There will also be a further reduction of £8 million in research and development expenditure, on top of the £30 million cut Mr Healey made in the last financial crisis. Nuclear weapon development will be cut by £2 million, and other savings will be made by not replacing wastage of civilians in defence establish-The Government had also decided not to build the staging post on Aldabra, although Mr Healey admitted that a decision had been made to go ahead, subject to approval from the American government. Aldabra would have been a valuable addition to British strategic flexibility, he said, but the Services must now forgo it. "I dare say that other sections of the community may see some benefits in this decision." The cancellation would save only £4 million this year, he said; the bulk of the reductions comes in the form of minor cuts and deferments. More than £60 million, he said, would be saved in this way. (Debate, November 27.)

Orbital Weapons

Orbital weapons may have the advantage of surprise, but would they be accurate?

A MONTH ago, on November 3, Mr Robert McNamara, Secretary of Defense in the United States, announced that he has evidence that the Soviet Union has developed a weapons system which consists of a rocket system for launching warheads into orbits about the Earth and then returning them on to predetermined targets. Studies now carried out in Britain suggest that the obvious advantages of such a system, chiefly surprise, will be to some extent at least outweighed by the disadvantages of increased inaccuracy.

According to reports from Washington, the evidence for believing in what is called the fractional orbital bombardment system consists chiefly of nine rocket launchings from the Soviet Union in the past few months. These have all consisted of brief flights in an orbit inclined at 50 degrees to the Equator and with a perigee and apogee of 145 and 210 kilometres respectively. The satellites which have caused particular concern are those known, from Russian announcements, to be Cosmos 139, 160, 169, 170, 171, 178, 179, 183 and 187.

It is also relevant, of course, that the then prime minister of the Soviet Union, Mr N. Kruschev, said in 1962 that the Soviet Union was to develop a rocket system which would enable warheads to be delivered on to their targets from any direction.

To function efficiently, a system of this kind must obviously involve an orbit which is low but yet sufficiently high to avoid serious consequences due to air drag. The element of surprise is the immediate attraction of such a system. Such a missile would be above the horizon from its target for about three or four minutes, but a ballistic missile on a course which spans a distance of 5,000 nautical miles would be visible to direct radars for the whole of 12 minutes—at least four times as long. But it is also plain that attacks with orbital weapons could be launched from any direction, at least if sufficiently powerful launch vehicles are available. With this system, it is also difficult for a defence to predict the point of impact even after an attacking missile has been identifiedeverything depends on when the retro-rocket is fired roughly 10 minutes before impact.

The snags, however, are considerable. For one thing, an orbital system would need a greater launching velocity than a ballistic missile, and the need to carry a retro-rocket implies either a larger launching vehicle or a smaller payload. Detailed calculations of the seriousness of these effects necessarily depend on the detailed characteristics of the rockets concerned, but a rough estimate would suggest that the payload of a rocket vehicle would be halved if it were converted to use in the orbital mode. In this rough estimate, the need for extra launching velocity seems to be decisive and responsible for three-quarters of the reduction of payload.

To make up in part for these disadvantages, it is of some importance that the orbital system could benefit from eastward launching directions. The benefit to be won in this way from the rotation of the Earth seems to be equivalent to roughly an extra 10 per cent of payload. In practice, of course, it would only be possible to take the fullest advantage of this small benefit

The chief disadvantage, however, of the fractional orbital ballistic system seems to lie in the increased inaccuracy likely to be involved. There are two sources of inaccuracy—the inaccuracy due to the inertial guidance system during the launching phase and the period of travel in a low orbit about the

by sacrificing a good deal of the element of surprise.

and the period of travel in a low orbit about the Earth, and the inaccuracy of the retro-rocket. The errors attributable to guidance seem to be greatest 180 degrees from the launching point and least in the

last quarter of the first orbit.

Naturally, the aiming errors depend very much on the types of errors involved in launching, but the sensitivity of the satellite orbits to errors at launching seems to be much greater than the sensitivity of ballistic rocket trajectories. Satellites intended for circular or nearly circular orbits are understandably affected to a quite remarkable extent by errors of vertical speed—a few feet per second can mean as many nautical miles of error at the end of the journey.

The errors due to the retro-rocket itself are likely to be greater. For the simplest retro-rockets based on solid propellants, miss distances of six nautical miles are possible. It is, of course, possible that the designers of an orbital weapons system would seek to diminish the importance of this source of error by carrying better retro-rockets into orbit, in which case the payload would be still further reduced. Errors of yaw (but not pitch) of the rocket at the point at which the retro-rocket fires might be responsible for a further miss distance of more than one nautical mile.

It is also relevant that the errors associated with the drag of the atmosphere in low orbits about the Earth may be quite considerable.

In these circumstances, it would seem that the errors realistically to be expected of guidance systems would be such as to make the orbital system a blunt instrument for use against targets where the errors are greatest. Lumping all the sources of error together suggests that the greatest miss distances might be more than seven nautical miles for the orbital system compared with 1.2 nautical miles for a ballistic missile. Even if the inaccuracy of the retro-rocket were eliminated by improving the system, the errors due to other causes would still be close on four nautical miles. Although it is theoretically possible to improve on this performance by the use of guidance stations near to the point of impact—ships or earth satellites—the chances are that such devices will be for some time impracticable.

Ît is also possible that the accuracy of the orbital bomb could be improved by providing for the weapon to complete one orbit of the Earth before homing on to its target. Accurate tracking during the preliminary orbit would enable the final accuracy of the weapon to be markedly improved, but there would be a loss of the element of surprise which seems to be the principal advantage of the orbital bomb.

Finally, it is worth remembering that this whole discussion may in the end turn out to have been academic. Russia has denied any intention of building a weapon of the sort described here, and the denial should not go unrecorded.

NEWS AND VIEWS

Nation of Astronomers?

At various times in the past decade, the Isaac Newton telescope has seemed something of a joke. The fact that the mirror blank was cast at the same time as the blank for Mount Palomar has occasionally made it seem a little like an afterthought. And the telescope has taken a great time to assemble, even by the standards usually applied to telescopes. Yet, now that it is complete, it is the visionaries and not the scoffers who are justified by events. The past few years have seen a considerable resurgence of interest in astronomy among British academics. It would be wrong, of course, to suggest that the solid line of achievement which goes back at least as far as Newton has at any point been broken, yet it has been something of a surprise to see how buoyant astronomy has become in Britain.

The Isaac Newton telescope is only the most tangible evidence of this development. Just a few weeks ago, there was the opening of Professor Hoyle's Institute for Theoretical Astronomy at Cambridge. Plans are also being hatched for a new steerable radio-telescope, at once bigger and better than any now in service. With luck, a decision to go ahead with the construction of this machine should have been taken by the early summer. By then, there should also be some signs of progress with the Southern Hemisphere telescope in Australia, which will eventually serve not merely as an instrument which British astronomers can use from time to time but also as a strengthening of the link in astronomy between Britain and Australia. The path between Mount Stromlo and Greenwich is well trodden, radio-astronomers in the two countries have learned a great deal from each other (which is not in any way to diminish the importance of the special relationship between Sydney and Cornell) and even Woomera seems to have stimulated scientists, not just engineers. But hardware is always less than half the story, which is why it is every bit as important that astronomy is coming to play a respectable part in academic studies of all kinds. In a sense, there is a kind of boom.

Why should this be? It is too much to hope for a simple explanation, for several disparate influences have played a part in what has been happening. The early start in radio-astronomy, at Manchester and Cambridge, has turned out to be immensely stimulating. Not merely do the radio-astronomers need an optical complement to their instruments, but the kind of work which they have done is itself suggestive of problems which other astronomers can tackle with optical telescopes or just with pencils and paper. But British astronomy has also somewhat paradoxically benefited from the lack of a gigantic space programme.

What has been happening elsewhere has sometimes stimulated interest and curiosity in extra-terrestrial phenomena, but harsh reality has suggested that traditional astronomy might be the most practical means of coming to grips with them. And sometimes, of course sheer perversity has made people strive, with splendid results, to do from the ground what other people say can only be attempted from an orbit about the Earth. At the same time, the influence of individuals has been important. The astronomers tend to be an energetic band of people, and they have in any case a natural cause on behalf of which to make propaganda. The theoreticians have been particularly well served by their advocates.

The administrative arrangements for the support of astronomy deserve particular attention, if only as models of how the development of other branches of science may be stimulated. The astronomers have been lucky. The old Department of Scientific and Industrial Research learned quite early on, from the radio-astronomers, that branches of science other than nuclear physics could be expensive. The department and the Science Research Council, which succeeded to its responsibility for astronomy, have been consistently far-sighted in their policies towards this branch of science. The fact that the scale of spending on astronomy has increased by what may be an order of magnitude in a decade is perhaps less important than the way in which the administrators have been willing to countenance sensible procedures—the arrangements by means of which British astronomers now have access to optical telescopes in South Africa and Italy are splendid examples of this flexibility. Although it would be wrong to suggest that all deserving causes are now adequately supported, the Science Research Council deserves a good deal of credit for what it and its predecessors have accomplished.

Certainly the agreement by which the SRC supports the Radcliffe Observatory in South Africa will be useful to British astronomy, and it is perhaps now unfair to complain about the long delay which preceded agreement on the Southern Hemisphere observatory.

Unfortunately it does not follow from this that the successes of the past few years will automatically be repeated in the future. One cause of difficulty is, of course, that like many other intellectual activities, astronomy is about to change quite radically. So much is clear from the article by the Astronomer Royal on page 855. Electronics has at last caught up with observational astronomy, with the result that the managers of telescopes can look for a substantial

improvement of the productivity of their instruments. The immediate goal seems to be to make the fullest use The instruments at present of image intensifiers. available—or promised—offer an advantage of a factor of twenty or thereabouts in sensitivity. In other words, half an hour of observation with a conventional photographic plate may be the equivalent of just over a minute with an image intensifier in the circuit. This is an enormous saving, and is recognizable as such even in places like California which are not so often plagued by clouds as the United Kingdom. The fact that image intensifiers are most advantageous in the red, where photographic plates are least efficient, may turn out to be a particular advantage. But the overriding gain is one that brings pleasure to the cost-benefit analysts. There can be few applications of electronics where so little equipment can bring such great benefits.

Yet it is too soon to throw hats a long way in the air. For one thing, the image intensifiers have to be fitted into observatory routine. Reliability is a problem that will be comparatively easy to deal with. There are greater problems in turning telescope domes into physics laboratories. And the image intensifiers are only a beginning. Soon people will be wanting to count photons—that could bring a further improvement of an order of magnitude. Then the time will no doubt come when people will ask whether it would not be better to make some telescopes largely automatic in their functioning. People, especially research students, may be cheap computers, but there is likely to be a strong flow of innovation from the techniques now being developed for earth satellites into the design of ground based telescopes. In other words, the time will soon come when the mirror blank is almost a trivial component of a telescope. Astronomers then will be cheerful people, but they will also be expensive. There are some signs that the Science Research Council is fully aware of the opportunities. The question it will have to answer soon is whether it will be able to back its judgement with the necessary funds.

Russian Machines

Some hints about the way Russian engineers are developing machine tools were given in a lecture to the Institution of Mechanical Engineers on November 22 by Professor I. I. Artobolevskii. Professor Artobolevskii, who is head of the Department of Applied Mechanics in the Institute of Machine Research of the USSR Academy of Sciences, had just been presented with the James Watt Medal, the institution's principal award. Because his predecessors include such eminent capitalists as Henry Ford, Academician Artobolevskii was understandably delighted to be the first Soviet scientist to get the award.

The chief problem facing industry in the next ten years, he said, was the transition to the complete automation of industrial processes. The whole concept of the machine itself had undergone significant change, now that it is possible to incorporate logical or control functions and to design cybernetic machines capable of replacing human organs. Professor Artobolevskii explained an important dialectical contradiction. "On

the one hand, automatic systems become more complex and specialized, the economy of operation of this expensive machinery being connected with the constancy of the design of articles and their mass production. On the other hand, technical progress involves constant innovation." This contradiction, he said, can be resolved by creating adaptable automatic systems capable of a rapid switch over from one product to another.

In years to come, he said, methods of chemical machining would come into operation which would eliminate many intermediate processes—die making and mechanical machining-which are characteristic of present day engineering. The problem of building automatic machines was closely connected with the problems of the theory of fluidics, and Soviet workers were developing a variety of pneumatic systems. He suggested that in the Soviet Union work was directed at the development of universal pneumatic systems on a modular basis for use in control systems. More recently, work on volumetric hydraulic drive had been considerably expanded; most of the calculations had been solved on electronic computers and simulators, he said, but on a much smaller scale than was desirable.

Trace Element Analysis

THE Society for Analytical Chemistry held a meeting on "Some Aspects of Inorganic Trace Elements Analysis" at the Atomic Energy Research Establishment, Harwell, on November 15. The ninety participants were welcomed by the head of the Analytical Sciences Division, Dr A. A. Smales, who pointed out that recent advances in materials science have emphasized the need for methods of measuring the distribution and chemical form of impurities in a wide range of materials, as well as for even greater sensitivity of measurement than is at present possible. Techniques particularly featured in the accompanying exhibitions included activation analysis, mass spectrometry, X-ray fluorescence analysis and emission spectroscopy.

During the afternoon, Dr R. K. Webster pointed out that although the isotope dilution technique based on thermal emission mass spectrometry is sensitive and accurate, only one or two elements are usually determined at one time. On the other hand, spark source mass spectrometry provides a wide coverage of elements in a single analysis, often with high sensitivity, but accuracy is limited unless suitable standards are available. He outlined a scheme for extending the isotope dilution method to the analysis of up to ten elements, including some of the alkali metals, and alkaline and rare earths, and showed that by applying the isotope dilution principle in spark source mass spectrometry the accuracy of the latter could be considerably improved.

Mr M. S. W. Webb described the use of a Q-switched ruby laser focused through a microscope to vaporize about a microgram of a sample from an area 50μ in diameter. By arranging for the vapour to short circuit two electrodes with an applied voltage of 2.5 kV, the spark spectra of the elements in the vapour can be recorded by conventional spectroscopy. ductors can be examined and the area to be analysed can be preselected. Examples were given to show the usefulness of the technique in assessing the homogeneity of materials and in examining inclusions.

There were also three papers on activation analysis. Activation by thermal neutrons is now well established. Because several active nuclides are usually present after irradiation it is necessary either to perform radiochemical separations or—in favourable cases—to use multichannel gamma spectrometry to measure active species. Mr D. Mapper described improvements in separation methods and the advance made possible by solid state detectors and the use of data processing and computer techniques.

There are some notable omissions from the list of elements which can be determined by thermal neutron activation. Dr C. A. Baker illustrated this with reference to three important impurities in metallurgy—carbon, nitrogen and oxygen. Irradiation with 30 MeV gamma rays produces radioactive neutron deficient isotopes—carbon-11, for example—which can be used to determine these elements at the p.p.m. level in samples weighing a few hundred milligrams.

Large and expensive equipment is required for activation by thermal neutrons and high energy gamma rays. Dr T. B. Pierce described the recent development of sealed-tube valve type neutron generators using the deuterium-tritium reaction. This makes possible a relatively inexpensive, compact system for the production of fast neutrons and is particularly suitable for the analysis of oxygen, aluminium, silicon, vanadium, chromium and titanium in intact metallurgical samples.

Inhibitory Synapses

from our Neurophysiology Correspondent

THE structure of the neuromuscular junction and of synapses in the central nervous system have been intensively studied by electron microscopists; it is fair to say that the physical basis for the storage and release of transmitter substances is well understood. Indeed, within the great diversity of synapses studied there is a "remarkable uniformity in the structures which are believed to be essentially concerned in their functional operation" (Eccles). Usually a presynaptic fibre expands to form a synaptic knob; within this, close to the presynaptic membrane, are large numbers of round vesicles between 300 and 600 Å in diameter. It is universally accepted (although most of the evidence is circumstantial) that the synaptic vesicles contain "packets" of transmitter molecules.

Recently Uchizono has suggested that there might be an anatomical basis for the recognition of excitatory and inhibitory synapses (Nature, 207, 642; 1965). Several authors have described synapses containing flattened, rather small, vesicles; Uchizono made the hypothesis that these were characteristic of inhibitory synapses. In the current issue of Experimental Brain Research (4, 97; 1967) he describes an attempt to correlate vesicular shape with synaptic function in the cerebellar cortex of cats. Eccles and his colleagues have used the cerebellar cortex as a model system because its structure is well known and conceptually simple. As they have been able to identify many of the gross anatomical features with specific physiological properties and in particular have shown which elements exert excitatory and which inhibitory effects, the cerebellum is ideal for Uchizono's purpose. The cerebellar cortex receives excitation through two sets of inputs—the mossy fibres and the climbing fibres. Mossy fibres synapse with granule cells in the "molecular" layer of the cortex: these give rise to axons which run vertically to the granular layer and there bifurcate, forming the parallel fibres which run along the long axes of the folds in the cerebellar cortex. As the course of the parallel fibres is so characteristic, their synapses are easily identifiable: They are known to be excitatory, and Uchizono shows that they contain spheroidal vesicles. The climbing fibres, which synapse with the dendrites of cerebellar Purkinje cells, are also known to be excitatory; their synapses contain spheroidal vesicles. On the other hand, the synapses of the basket cells, also easily identifiable, are known to be inhibitory: these contain ellipsoidal vesicles. Other synapses containing flattened or ellipsoidal vesicles are tentatively identified as belonging either to stellate or basket cells, both inhibitory.

So far, then, the evidence from the cerebellar cortex supports Uchizono's hypothesis. Several objections, however, have been made to it: Andersen and others have suggested that identification of the origin of a terminal axon can only be certain when supported by degeneration studies. However, it seems reasonable to accept Uchizono's claim of unequivocal identification on the grounds of our knowledge of cerebellar structure. It has also been suggested that ellipsoidal vesicles are fixation artefacts. While it is known that this can be so, several of Uchizono's electron micrographs show neighbouring structures containing round and ellipsoidal vesicles. A more serious possibility is that the same transmitter might be shown to have opposite effects in different synapses—as acetylcholine has on heart muscle and skeletal muscle—for presumably one type of transmitter inhabits only one sort of vesicle. Unequivocal support for Uchizono's hypothesis can only come from identification of the transmitter molecules in the two types of vesicle. Even so, it is at the moment more successful than the previous attempts to link synaptic structure with function.

Algal Toxins

from our Microbiology Correspondent

In comparison with bacterial and fungal toxins, algal toxins have had little attention. This is somewhat surprising because algae cause the well known fresh water and saline toxic blooms and "poisonous red tides", which present hazards to the health of humans, domestic animals and marine life. Indeed, some algal toxins are among the most potent known; that of Gonyaulax catenella, for example, has a lethality approaching that of botulin. Plankton-feeding shellfish have been implicated as vectors of algal toxins, but for the intoxication of other aquatic animals large scale toxin release induced by autolytic, bacteriolytic or algal virus action appears to be a pre-requisite. So far very few algal toxins have been characterized chemically: that of G. catenella is a substituted purine while Microcystis aeruginosa produces a cyclic polypeptide toxin containing D-serine. The mode of action of these substances involves the blocking of axonal and muscle conduction by disturbing sodium or calcium conductance. Apart from studying the production of algal toxins from the viewpoint of animal intoxication, it would also seem profitable to use these substances as tools in the investigation of excitable membranes and also to evaluate their possible antibiotic activities.

Studies in this sphere have been in progress for a number of years at the Hebrew University in Jerusalem, and Dr Moshe Shilo has reviewed recently the current state of knowledge (Bacteriol. Proc., 31, 180; 1967). The Jerusalem school selected the halophilic chrysomonad Prymnesium parvum as a model system, because it is an alga which produces an exotoxin complex responsible for high fish mortality in Europe. Toxic effects include haemolysis, disturbance of gill permeability and cytopathogenicity; other less well defined toxic components induce numerous pharmacological activities in nerve and muscle preparations. The toxins are formed during late exponential and stationary phases of growth, and light is essential for their production (heterotrophically grown cultures in the dark are non-toxic). One of the most interesting and intensively investigated Prymnesium toxins is ichthyotoxin. This toxin requires a divalent cation co-factor and its activity is stimulated by polyamines such as spermine. These co-factors do not function additively and ichthyotoxin activity is the resultant of their complex interaction. Ichthyotoxin induces marked and rapid changes in gill permeability and sensitizes fish to many other non-specific poisons. This toxin has many of the properties of surface active agents and anionic detergents clearly simulate its action. The activated toxin is considered to form a polymolecular micelle and thereby resembles plant

Prymnesium is killed by very low levels of ammonia and other weak electrolytes including acetic acid, and this sensitivity has provided the basis of control measures under field conditions. The electrolyte activity is pH-dependent, which suggests that undissociated molecules and not ions are involved in the killing of the alga. Shilo proposes that osmotic imbalance is established in the alga by the retention of undissociated electrolyte molecules and that this leads to lysis and death. It is significant that other halophilic micro-organisms such as luminous marine bacteria also are sensitive to weak electrolytes and this sensitivity may be a general feature of cells which develop under conditions of extreme osmotic stress.

Ultraviolet Light and Cell Growth

from our Cytogenetics Correspondent

IT is well known that ultraviolet light can cause damage tonucleic acids and that in some cases this damage can be repaired in visible light. Ultraviolet light also prevents cell division and growth, but the physiological basis of this effect and whether it too can be repaired is less well understood. Employing a microbeam of ultraviolet light, Brown and Zirkle (Photochem. Photobiol., 6, 817; 1967) attempted to characterize precisely what is damaged when cell division is halted. A beam 8µ in diameter was focused onto the cytoplasm of cultured axolotl cells approaching metaphase. By varying the wavelength of the light, an action spectrum for the arrest of chromosome movement at anaphase and mitotic spindle destruction was drawn up. The most effective ultraviolet wavelength in arresting both these processes was found to be 277.5 mµ, and the action spectrum follows fairly closely the ultraviolet absorption spectrum of proteins containing tyrosine and tryptophan. So it is possible that some protein in the cytoplasm is damaged by the microbeam and this results in an impairment of function of the nearby mitotic spindle. Could the protein be an enzyme essential for spindle integrity? The action spectrum fits quite well the spectrum for inactivation for at least one enzyme, aldolase, so enzyme damage is a clear possibility.

The mitotic spindle has much in common with the sub-units of flagella. Earlier this year Hipkiss reported in Radiation Botany (7, 347; 1967) that when the unicellular alga Chlamydomonas was irradiated with sub-lethal doses of ultraviolet the flagella immediately become detached from the cell. Probably structural proteins at the base of the flagella are damaged causing the latter to break off from the cell.

The effect of near ultraviolet (365 m μ) on growth of Ginkgo pollen culture and human HeLa cells has been investigated by Klein and Edsall (Photochem. Photobiol., 6, 841; 1967). They find this wavelength most effective in repressing growth of both cell types. Repression of the HeLa cells can be reversed by a period of darkness, but only if it is longer than 15 minutes within an hour-long dark-ultraviolet light cycle. Green light also repressed growth of the two cell types; this cannot be reversed by dark but can be reversed by red light. Other differences between near ultraviolet and green light inhibition are that in both cell cultures ultraviolet light inhibits the early phases of growth while green light inhibits the later phases; and in onion roots Wolff, Fives and Klein (Bull. Torrey Bot. Club, 94, 411; 1967) report that near ultraviolet light slows down the prophase stage of mitosis but green light slows the anaphase stage.

To complicate matters, however, Klein, in earlier publications this year, showed that near ultraviolet light can reverse the effect of ultraviolet light at 254 mµ on leaf fall in Coleus plants (Ann. N.Y. Acad. Sci., 144, 146; 1967). Also, in a number of other plant systems, including the Ginkgo pollen cultures, the repression of growth by ultraviolet light at 254 m μ can be reversed by blue light (Amer. J. Bot., 54, 904; 1967). So far there are no adequate explanations for any of these findings. In the plant systems investigated it is likely that ultraviolet light accomplishes some of its effects through damaging internal auxin (growth hormone) functions. Only a fuller investigation of the effect of light of different wavelengths on proteins, enzyme function and nucleic acid metabolism will reveal more positive answers.

Polymerase Activity and Dissociation

from our Molecular Biology Correspondent

An interesting example of the control of enzymic activity by an association-dissociation equilibrium is provided by the important enzyme, DNA-dependent RNA polymerase. This is a large protein with a sedimentation coefficient, under the usual conditions of preparation, of about 24S. It has been shown that the enzyme will dissociate in response to changes in ionic strength or pH. Smith et al. (Biochemistry, 6, 3057; 1967) have now examined the effect of the template on the association equilibrium; for this purpose it is necessary to use a small template and not a high molecular weight DNA, which would be large compared with the enzyme itself and would contain many initiation sites. Using oligomers of deoxycytidylic and adenylic acids, the authors have made the interesting discovery

that addition of such templates causes a displacement in the association equilibrium in favour of a dissociated form. Thus with a ratio of nucleotide to enzyme of 0·4, a 19S component appears, and this is followed at higher ratios by one of 13S. At limiting nucleotide concentrations, only the last is present. Removal of the oligonucleotide by digestion with a nuclease reverses the reaction. These new components of the enzyme have been recognized before, and it has been supposed that the 19S and 24S states represent the dimer and trimer respectively of the 13S unit. The 13S form is evidently highly active, for it is observed that at elevated salt concentrations, at which the enzyme dissociates, its activity relative to a native DNA template is increased.

This latter observation is confirmed by So et al. (Proc. US Nat. Acad. Sci., 58, 1739; 1967), who have demonstrated enhanced activity in 0.2 M KCl solutions, using several DNA species as templates. Moreover, when the enzyme concentration is very high indeed, no such stimulation is elicited. So et al. suggest that under these circumstances all the initiation sites on the template DNA may already carry a polymerase molecule, so that an increase in the number of independent enzyme molecules through dissociation no longer has any effect. Alternatively, of course, the dissociation of the enzyme may be substantially less at such high concentrations; dissociation will in any case not be favoured by the low template to enzyme ratio.

It is also noted that the reaction at high salt is no longer subject to product inhibition, and so does not cease after a relatively short time, as it does at low salt concentrations. A further effect of the potassium chloride appears to be the suppression of non-specific RNA synthesis (polymerization without correct copying).

with denatured DNA it was observed that when the enzyme in 0.2 M KCl was added to the reaction mixture, addition of KCl now failed to produce the expected result. This is attributed to the instantaneous binding of the dissociated enzyme to the single strands; once bound, it is unable to aggregate again, so that no further disaggregating effect ensues on introduction of potassium chloride. If, on the other hand, the enzyme is added from a solution of low ionic strength, so that it enters the reaction mixture as 24S particles, the enhancement of activity by added potassium chloride is again observed. These results are not incompatible with those of Smith et al.: both high template to enzyme ratios and the added salt are factors which promote dissociation and activity.

So et al. note finally that different univalent cations vary in the degree in which they stimulate the polymerase activity. Whether this arises from differences in their efficacy in promoting dissociation or some other kind of action is not known.

Dynamics of RNA Synthesis

from our Cell Biology Correspondent

Schlessinger's group has shown that the ribosomal population $E.\ coli$ consists of free 30S and 50S sub-units and polysomes without a pool of free 70S ribosomes, and as I mentioned two weeks ago (see Nature, 216, 638; 1967), these observations agree with the latest ideas about chain initiation. In the current J. Molecular Biology (29, 395; 1967) Mangiarotti and Schlessinger

report further kinetic studies of the formation and lifetime of $m{\rm RNA}$, ribosomal sub-units and polysomes which provide more evidence for many of the now almost conventional ideas about transcription and translation.

Mangiarotti and Schlessinger uniformly labelled all the stable RNA in a fragile strain of *E. coli*, which is easily lysed, with C¹⁴ uracil and then switched the cells to a medium containing H³ uracil. The ratio of H³ labelled RNA to C¹⁴ labelled RNA is then a measure of the ratio of new to old RNA molecules. Under their growth conditions complete chains of ribosomal RNA are synthesized in 1 to 2 minutes and it takes at least another 5 minutes to convert the ribosomal RNA into 30S and 50S sub-units by the addition of protein. They claim, unlike earlier workers, that it takes the same time to make either type of sub-unit. Not surprisingly, synthesis of ribosomes in *E. coli* is much quicker than in mammalian cells (see *Nature*, 214, 963; 1967).

The specific activity of the label in free 30S and 50S sub-units and that in sub-units of the 70S monomers of polysomes increases at an identical rate. This means that there is rapid exchange between a pool of free sub-units and the sub-units of 70S ribosomes in polysomes. Furthermore, ribosomal RNA never appears in polysomes in an incomplete form. This is more evidence that ribosomal RNA does not act as mRNA (see Nature, 214, 963; 1967). It also means that the attachment of ribosomes is not necessary for the release of ribosomal RNA from its DNA template.

About 30 per cent of the total H3 uracil incorporated within 6 minutes of giving the label, in other words before new ribosomal sub-units have been completed, is in mRNA. Virtually all the mRNA-about 3 per cent of the total cellular RNA-detectable at any time is in polysomes. These results confirm other evidence that translation begins before transcription has been completed and moreover it shows the mRNA molecules must be functional for almost all their lifetime, which on average is 11 to 12 minutes. Under different conditions Forchhammer and Kjeldgaard (J. Mol. Biol., 24, 459; 1967) found that about half the mRNA in a mutant strain of E. coli has a half-life of about 5 to 7 minutes whereas the other half was relatively stable with a half-life of between 42 and 70 minutes. Clearly the stability of mRNA in E. coli is very dependent on the strain and growth conditions.

In eucells mRNA is generally more stable than in bacteria, but even so in several situations its stability depends on whether or not the cells are dividing; stability increases as the cells lose their mitotic activity. Stewart and Papaconstantinou have just reported an interesting example of this (J. Mol. Biol., 29, 357; 1967). Bovine lens epithelial cells synthesize three closely related proteins, α , β and γ crystallin. Actinomycin D completely inhibits crystallin synthesis in embryonic cells but not in adult cells, although in both cases all RNA synthesis is inhibited. The embryonic cells actively divide whereas the mitotic index of the adult cells is low. Stewart and Papaconstantinou infer from this that as epithelial cells age the mRNA molecules which specify crystallin become stabilized and this stabilization may well be related to the decrease in mitotic activity of the ageing cells, but how it is effected is a mystery.

Recipe for Nuclear Power

NIGEL HAWKES

The Select Committee argues in favour of a single design authority —but not everyone agrees.

THE Select Committee on Science and Technology makes one bold recommendation in its report on the British nuclear power programme, published last week (HMSO, £2 19s.). It says that future nuclear power stations should by designed and built by one central organization, which would incorporate parts of the Atomic Energy Authority and the existing nuclear consortia. Whether or not the committee would back such a central organization was the main doubt behind its deliberations, because the idea divides the nuclear power industry in Britain down the middle. The select committee itself was in two minds and finally decided on the central authority by a majority vote, 7 to 5, with one Labour member abstaining. For the rest, the recommendations are uncontroversial, even mundane.

At times, the report gives the impression of a committee so anxious to pick a winner that it was prepared to back every horse in the race—and some not even running. High temperature reactor development should be intensified, with particular emphasis on the Dragon system. Water reactors, and the steam generating heavy water reactor at Winfrith, should also be speeded up. Yet another survey, this time by the Ministry of Technology, should be made of fusion research, although if the committee wants more support for fusion, it should have asked another body to do the job—the ministry has already made its attitude perfectly plain. And the committee also finds the courage to say a few kind words about marine nuclear propulsion; here it recommends a departmental committee to look into the possibilities.

These detailed proposals can, of course, be quietly pigeon-holed if they do not suit the ministry's ideas. It is far less easy to dodge the central recommendations which the committee makes. For one thing, it is probable that the move away from turnkey contracts already set gently in motion by the Central Electricity Generating Board will be accelerated by the committee's approval. And the British Nuclear Export Executive, in existence for only 18 months, always seemed likely to become the whipping boy for the industry's failure to export, although, until the Dungeness B assessment in 1965, the product was wellnigh unexportable except as a curiosity. BNX should be wound up, the report concludes, to be replaced by "an intensive survey" of overseas markets by the Board of Trade, the Atomic Energy Authority and the engineering companies.

It is in the debate about the future of the Atomic Energy Authority that the committee is likely to have its greatest impact. The Minister of Technology, Mr Wedgwood Benn, has looked in the last few months like a man waiting for his mind to be made up, and the report could just do the trick. This is not to say that he will necessarily agree with it in every detail, but certainly the central design authority now looks a likely bet. Under the com-

mittee's scheme, the AEA would be divided into four groups. Those parts of the authority which are concerned with the design and construction of nuclear boilers would go into the central authority or company. The pure research work of the authority would remain as a rump organization, with a stern admonition not to let its attention wander into fields outside nuclear energy. There would also be the fuel processing and fuel element construction side of the authority, which some companies in the private sector should be allowed to join, and a defence research organization continuing the authority's work in the nuclear armament field.

Dr J. M. Hill, Chairman of the AEA.

This bears some resemblance to the arrangements which the authority, in the person of Lord Penney, itself put forward. This may explain why the authority has given the report a cautious welcome. In the official wording—"The authority are gratified that a decision much like their own has been reached". But the authority also makes warning noises about the dangers of fragmentation, particularly in fuel element manufacture. And the detailed operation of splitting the authority into four might turn out to be even less good for morale than the long period of uncertainty which the authority has survived. There should be no doubt about what the proposals actually mean: the report says "The AEA as we know it today may well disappear". Mr Arthur Palmer, chairman of the committee, puts it this way—"What we're suggesting is the breaking up of the AEA".

If the proposal is adopted, much will hang on the exact proportion of the equity of the new organization which the AEA will hold. Mr Palmer said that the AEA would be in a "dominant" position, but later admitted

that this might be putting it too strongly. Mr Eric Lubbock, another member of the committee, believes strongly that the AEA should not dominate the organization. The sort of figures which are being talked about—and which alarm Conservatives—are that the authority should hold about 35–40 per cent of the equity of the nuclear boiler organization. But there is also some evidence that the Government is thinking again, and may modify this figure. Mr S. A. Ghalib, managing director of the Nuclear Power Group, thinks that the exact figure may not be important—"provided that it's less than 50 per cent".

50 per cent". The Central Electricity Generating Board is happy, naturally enough, that the report endorses its own views on the competitiveness of nuclear stations. The report also backs up the board in suggesting that the second nuclear power programme should be slightly larger, something which Mr Richard Marsh, Minister of Power, may be considering. The board accepts, too, that turnkey contracting is on the way out. But behind the assurances it is clear that the CEGB will not be very enthusiastic about dealing with a monopoly supplier of nuclear knowhow—and it is also likely now to claim that its expenditure on laboratories, which will give it technical independence. was doubly justified. Just how unhappy the board will be to deal with the single boiler company is difficult to assess -an official last week suggested that the board would not be particularly hostile. "But we would have preferred two competing groups," he admitted.

The report does not close the door entirely on commercial competition. It says that the CEGB must be willing to invite tenders from abroad for nuclear boilers—in effect, this will mean from the two largest groups in the United States, Westinghouse and General Electric. This is, in fact, a generous recommendation, because it is extremely unlikely to be reciprocated. The very restrictive United States trade policy, enshrined in various "Buy American" Acts, makes certain of this. For political reasons, therefore, a tender from the United States would be most unlikely to be accepted unless it was made through a British licensee—a loophole which may allow some independent British firms to stay in business. The committee also indicates that links between British and European firms might allow the market to be widened. Mr

Ghalib points out that TNPG already has arrangements with Belgonucléaire in Belgium and Snam Progetti in Italy, and is clearly hoping that this sort of agreement may be a way of maintaining competitiveness. But it must be admitted that the removal of commercial competition at home, combined with an acceptance of foreign tenders, is a rather contradictory position for the committee to have adopted. If competition is good internationally, it ought to have at least some merits nationally. Most of these points are made by Conservative members of the committee, in an amendment proposed by Mr David Price which sought to overturn the recommendation for a single authority.

With the publication of the report, the nuclear power industry moves from one period of uncertainty into another. However quick Mr Wedgwood Benn may be in coming to a decision, reorganization cannot take place overnight. The existing consortia will presumably have to work out their present contracts, because a changeover to a new organization halfway through a contract would really be rather wasteful of time and effort. It is sobering to realize that there are still two Magnox stations, Oldbury and Wylfa, to be completed. After that will come Dungeness B in 1970-71, Hinkley Point B in 1972, and Hunterston B in 1973.

One of the interesting aspects of the report is the light it sheds on relations between the select committee and various government departments. The Ministry of Technology seems to have been very correct, except in its refusal to publish the report of the committee which recommended the reductions at Culham Laboratory. The Ministry of Power, on the other hand, is sharply criticized for failing to produce quickly enough a document promised to the committee by Mr Richard Marsh. And the Foreign Office seems to have been deliberately obstructive when the committee sent two sub-committees abroad, although the embassies abroad—and particularly in Bonn were very helpful indeed. The report of the subcommittee which went to Europe has a terse reference to the scale of expenses allowed-which, although it is not quoted, is believed to be £1 a day—forcing the members to entertain out of their own pockets. "The members to entertain out of their own pockets. financial provisions must be improved in future," the report says.

The Isaac Newton Telescope

by
Sir RICHARD WOOLLEY
Astronomer Royal

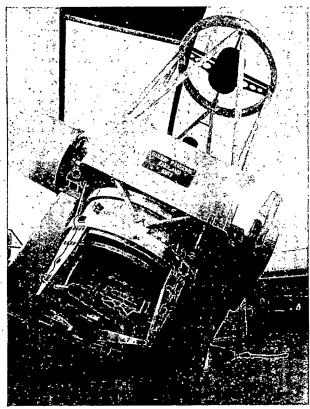

The largest telescope in Britain has been inaugurated in the past week.

The Isaac Newton telescope, which was inaugurated by the Queen on December I, 1967, is a parabolic reflector of 98 in aperture and a primary focal ratio of 3.03. It is equipped with a Cassegrain focus at f/15 and a coudé focus at f/32. At these foci the scales are 27.5"/mm, 5.5"/mm and 2.7"/mm respectively.

That the telescope has been built is a tribute to the advocacy of Professor H. H. Plaskett, then President of the Royal Astronomical Society, as long ago as 1946. Although agreement in principle by the Treasury and the Admiralty to provide funds for the instrument was reached in the following year, the project was delayed for a number of years and the contract for its construction, by the firm of

Sir Howard Grubb, Parsons and Co., was not placed until 1959, since when the manufacture and erection have proceeded at the rate which has been accepted as normal in all large telescope projects. The Admiralty having transferred the administration of the Royal Greenwich Observatory to the newly formed Science Research Council, the council has become the authority responsible for the Isaac Newton telescope. The council has vested the responsibility for the maintenance of the telescope in the Royal Greenwich Observatory, in whose grounds at Herstmonceux the telescope stands; but the observatory has no special claim on the time available for observing with it. In fact the Science Research Council has set up a Large

Telescope Users' Panel, which will consider applications for the use of the telescope from all British astronomers. It is expected that the panel will be in a position to allocate observing time in the last quarter of 1968, for which it will be prepared to consider applications at Easter, 1968.

The 98 in. Isaac Newton telescope.

The telescope has a fork mounted in a novel way, for it is based on a large disk (22 ft. in diameter) mounted in the equatorial plane rather than on a polar axis. The use of the disk has enabled the designers to use very massive tines for the fork, and it is anticipated that these will suffer very little flexure. A second novel feature is the use of an air bag for the support of the mirror. The mirror must, of course, be located at three points, but if these three points sustained the entire weight of the mirror there would be intolerable flexure, resulting in deformation of the optical surface. This difficulty, which has, of course, been recognized for a century, has been overcome in the past by the provision of a number of floating supports—that is to say, mechanical levers. The ideal support is flotation, which is, of course, ruled out, since the telescope must point anywhere from the zenith to the horizon. Support with an air bag achieves the same uniformity as liquid flotation but suffers the difficulty that the air pressure must be made to vary from zenith (bearing the full weight of the mirror) to the horizon, where the weight to be borne is zero. The Isaac Newton telescope mirror support incorporates a system which is designed to adjust the pressure in an air bag under the mirror to the correct value. The mirror must clearly have a side support as well as a back support, and in order to avoid deforming the mirror surface it is necessary to arrange that the two supports do not compete; the permitted coefficient of friction is less than 1 per cent.

The primary mirror weighs four tons. The blank is of 'Pyrex' glass and was cast at the same time as the blank for the 200 in. telescope at Mount Palomar. It was presented to the Board of Management originally respon-

sible for the telescope by the trustees of the McGregor Fund through the offices of the late Astronomer Royal, Sir Harold Spencer Jones. The mirror can be lowered from the observing floor to the ground floor—where there is an aluminizing tank permanently located—by means of a crane which is carried by the dome of the telescope. The secondary mirrors are all made of quartz.

Despite the comparatively modest aperture, the telescope carries a prime focus cage in which an observer can sit and carry out direct photography. At the Cassegrain focus there is an observing chair attached to the telescope, so that the observer can follow the telescope wherever it goes in a long exposure. No problem of locating the observer arises, of course, at the coudé focus.

The Royal Greenwich Observatory has completed the manufacture of a special Cassegrain spectrograph for use in conjunction with the Isaac Newton telescope. This will shortly be adjusted and mounted on the telescope. There is a large space provided for a coudé spectrograph. This has been designed and some part of the manufacture has been commenced, but it is not expected that the coudé spectrograph will be in operation before the end of 1968.

It is, of course, expected that image intensifiers will play a dominant part in the use of the Isaac Newton telescope in years to come, and active plans to bring these into practical operation are currently being made by the Royal Greenwich Observatory in close co-operation with Professor McGee of Imperial College, and with Dr Wynne of the same college. Efficient use of the new sensors demands the design and construction of special cameras to combine low focal ratio with ease of access to the focus, and Dr Wynne will be designing these.

It is not possible to say how the telescope will be used, as it is open to any astronomer to make any proposal to the Large Telescope Users' Panel. The facilities already mentioned (direct photography, Cassegrain spectrograph, coudé spectrograph, possibly image intensifier spectrographs) may be generally available to investigators in 1969 or 1970. It appears very likely that direct photography of interest to radio astronomers will be undertaken at an early date.

The climate of Herstmonceux is, of course, inferior for astronomical purposes to the climates of desert and semi-desert areas in lower latitudes, but it is likely that some work can be undertaken on at least 40 per cent of the nights of the year. It is not advisable to set out on a long exposure unless the night sky is clearer than usual and the weather forecast is good—conditions which obtain on perhaps 20 per cent of all nights. Observers who have had time allotted to them will be expected to maintain a constant watch for breaks in the weather, if they are not actually working, and the SRC will maintain at all times at least one of its own personnel in the dome with instructions to see that the telescope is properly used and not put at risk. It is intended to set up arrangements to accommodate outside observers at Herstmonceux Castle for their observing periods.

The telescope may be expected to give a powerful stimulus to British optical astronomers, and to produce results of first-class scientific value, if due attention is paid to sophisticated instrumentation.

As has already been announced, the Science Research Council is co-operating with Australian authorities in setting up an Anglo-Australian telescope of 150 in. aperture. This telescope will be located on Siding Spring mountain, near Coonabarabran in New South Wales. Some of the time on this telescope may be reserved for the use of a permanent staff, and the remainder will be divided between United Kingdom and Australian observers. It is intended that the UK share in the time of this telescope will be distributed by the Large Telescope Users' Panel. It is unlikely that the Anglo-Australian telescope will be commissioned until about 1975. Its existence will, of course, enlarge still further the opportunities available to British astronomers of the future.

Actions of Thrombin and Other Coagulant and Proteolytic Enzymes on Blood Platelets

by M. G. DAVEY* E. F. LÜSCHER

Theodor Kocher Institute, University of Berne, Switzerland The action of thrombin on fibrinogen is not responsible for its effect on platelets. Thrombin does, however, have an enzyme effect on a platelet constituent: this requires an unsubstituted serine hydroxyl group and a group susceptible to acetylation.

THROMBIN is a proteolytic enzyme resembling trypsin in specificity1. It can be postulated that both its coagulative action and its effect on platelets follow proteolytic reactions. Fibrinogen, the principal natural substrate of thrombin, is present in platelets² and it has been suggested that the platelet "release reaction" follows the hydrolysis of susceptible arginine-glycine peptide bonds in fibringen on the platelet surface3. To establish this mechanism it is desirable to show that other enzymes capable of clotting fibrinogen will cause a release reaction when applied to platelets. Such enzymes are trypsin4, papain⁵, and a number of coagulative substances in snake venoms, particularly of members of the family Crotalidae^{8,7}. We have reported studies of the actions of a number of these venoms8,9: two which were potent coagulants of fibrinogen caused no changes in platelets and five with similar coagulative actions also caused a release reaction. At the time we proposed that both effects could be caused by one thrombin-like constituent. We now report further studies which have proved that this proposal was wrong, and we also report some experiments with other proteolytic enzymes and with a "thrombin" formed by the action of a bacterial coagulase.

Suspensions of washed human platelets were prepared in isotonic media buffered with *tris*¹⁰. The morphological changes and the release of nucleotides after various agents were added were studied as before. The total amino-acid content of perchloric acid extracts of platelets and supernatants was determined by a ninhydrin reaction¹¹, using glycine as a standard. We studied venoms of the yafara, Bothrops jararaca, and the himehabu, Trimeresurus okinavensis (both from Koch-Light Laboratories, Colnbrook, Buckinghamshire), the shore pit viper, T. purpureo-maculata, and the tropical rattlesnake, Crotalus t. terrificus (gifts from Professor R. G. Macfarlane), the Malayan pit viper, Ancistrodon rhodostoma (given by Dr M. P. Esnouf), and the eastern diamond-back rattlesnake, C. adamanteus (Ross Allen's Reptile Institute, Silver Springs, Florida). All contain coagulants of fibrinogen and all but those of A. rhodostoma and C. adamanteus provoke a release reaction⁹. Venom solutions which were kept for any period were stored at -20° C. Bovine thrombin (63 N.I.H. units/mg) was given by Hoffmann-La Roche, Basle.

The enzyme preparations used were crystalline trypsin (C. F. Böhringer, Mannheim), papain and α-chymotrypsin (Worthington Biochemical Corp., Freehold, New Jersey) and "pronase" (Streptomyces griseus protease, grade B, Calbiochem, Los Angeles, California). Fresh enzyme solutions were prepared for each experiment. Human "coagulase thrombin" was prepared at the Centre National de Transfusion Sanguine, Paris, by the activation of partly purified human prothrombin with staphylocoagulase¹²—kindly given by Professor J. P. Soulier. The preparation contained the equivalent of 8 N.I.H.

*Present address: Red Cross Blood Transfusion Service, Perth.

clotting units of thrombin/mg of protein. Hirudin (VEB Arzneimittelwerke, Dresden) was a gift from Professor F. Markwardt. Diisopropylfluorophosphate (DFP; Calbiochem) was dissolved in analytical grade isopropanol at a concentration of 0·2 moles/l. This was added to aliquots of venom or enzyme solutions (1–2 mg/ml.). The greatest final concentration used was 0·01 molar DFP (5 per cent isopropanol) and mixtures were kept for at least 2 h at room temperature (20°–22° C) before testing. Fibrinogen clotting times were determined as before. Esterase activities were measured by a formol titration method using toluene-p-sulphonyl-1-arginine methyl ester (TAMe) as substrate¹³.

Electrophoretic separations of venom components were performed in layers of 1 per cent agarose (Serva, Heidelberg) in 0.05 molar veronal-hydrochloric acid buffer, pH 8.2, on glass slides. Proteins were stained, after fixation, with amido black 10B. Esterase activity was detected by covering the unfixed layers with 0.2 molar TAMe containing 0.1 per cent phenol red; yellow zones indicated hydrolysis. Other unfixed layers were cut into 4 mm strips which were eluted with 0.3 molar sodium chloride, and the cluates were assayed for coagulant and esterase activities and actions on platelets.

esterase activities and actions on platelets.

Reaction of thrombin with DFP inhibited its effect on platelets to the same extent as its esterolytic and coagulative actions. The venom of B. jararaca behaved similarly but with the venoms of C. terrificus, T. okinavensis and T. purpureomaculata the esterolytic and coagulant activities could be abolished without reducing their release of platelet nucleotides (Table 1). On electrophoresis, each of the Trimeresurus venoms showed four or five protein bands, two of which had esterase activity. Coagulant activity was eluted with the faster moving esterase fraction in each case. Material which produced a release reaction was eluted independently of the coagulant in both. The thrombin preparation showed a number of protein bands, but esterase, coagulant and nucleotide-releasing activities were all found in the same fraction (a β -globulin).

With the help of Dr M. P. Esnouf (Radcliffe Infirmary, Oxford), the substance in T. okinavensis venom which

Table 1. INHIBITION OF THROMBIN AND VENOM ACTIVITIES BY DEP

Test	Fibrinogen clotting time (sec)		TAMe esterase (µmoles/mg/h)		Platelet nucleotide release (per cent)*	
(0.04 mg)	Intact `	DFP	Intact	\mathbf{DFP}	Intact	DFP
Thrombin B. Jararaca venom C. terrificus venom T. okinavensis venom T. purpureomaculala venom	5 37·2 65·6 26·3 71·0	> 2,400 > 2,400 2,000 > 2,400 1,200	65 280 101 827 210	0 5 6 8 4	61 46 62 55 56	24 33 62 53 56

^{*} Means of three experiments: Control, 20-25 per cent. Test substances were incubated with aliquots of platelets (14-19 mg total protein) for 15 min at 37° C. Concentrations of DFP were 5 mmolar in original solutions of thrombin and venoms, 0.1-0.2 mmolar in incubation mixtures.

releases nucleotide has been separated from the coagulant and other esterolytic and proteolytic components: these results are to be published. So far, the material seems to be of quite high molecular weight (about 500,000), contains some protein and a large proportion of carbohydrate and induces the release of ADP from platelets in plasma at concentrations as low as five to ten molecules for each platelet. No enzymatic activities have been identified. No other fraction of the venom has any effect on platelets. including those with coagulant, esterase, protease and phospholipase A activities.

Table 2. Effects of protrolytic enzymes and thrombin on platelet nucleotide and amino-acid content

	Nucleotide release Free a (per cent) Supernatants		mino-acids (µmoles) Platelets Total	
Control Thrombin 10 units Trypsin 0·1 mg	21 57	1·8 2·6 4·4	5·5 4·9 4·8	7·3 7·5 9·2
Papain 0·1 mg Pronase 0·1 mg Chymotrypsin 1·0 mg	69 56 62 28	4·2 5·4 3·2	5·1 5·3 4·9	9·3 10·7 8·5

Test materials were added to platelet suspensions containing 32 mg total protein and 5 $\mu\rm moles$ CaCl₂ in 1 ml., and incubated for 15 min at 37° C.

Of the purified proteolytic enzymes tested (Table 2), trypsin, papain and pronase, in low concentrations, caused release of platelet nucleotides with associated platelet aggregation and contraction of aggregates. When larger amounts were applied, stable platelet aggregates did not form. Chymotrypsin, up to 1 mg/ml., had no such action. All four enzymes produced large amounts of free aminoacids and peptides in the supernatants but the amounts within platelets did not alter. The effects of the three active enzymes were inhibited in part by removing calcium from the suspensions or by adding hirudin. Trypsin and pronase were also inhibited by DFP, and papain by preincubation with N-ethylmaleimide. agulase thrombin, compared with equivalent coagulant amounts of bovine thrombin, did not alter washed platelets (Table 3). Finally, washed platelets were incubated with coagulants shown to have no nucleotidereleasing effect such as A. rhodostoma and C. adamanteus venoms. After washing, aliquots were exposed to thrombin. Preincubation did not modify the effects of thrombin in any instance (Table 4).

Some conclusions from these experiments are set out in Table 5. The Bothrops venoms are put in a doubtful category, because it has not been possible until now to separate their two coagulant activities (factor X activation and direct clotting of fibrinogen?) from their action on platelets. The latter may be the result of a thrombin-like enzyme or, as was earlier suggested, the activation of factor X, and thus of prothrombin, on the surface of platelets. Other studies of the release of platelet serotonin and nucleotides by snake venoms have also shown that venoms of a number of Bothrops and Crotalus species were active¹⁴. For C. terrificus, this activity could be distinguished from coagulant, protease and phospho-

Table 3. ACTION OF BOVINE THROMBIN AND COAGULASE THROMBIN ON

	PLAT	ELETS

* Not congulative.	T. okinavensis	

lipase A activities also present in the venom; it was not inhibited by DFP.

These results make it impossible to maintain that the enzyme action of thrombin on fibrinogen is also responsible for its effect on platelets. They do, however, indicate an enzyme action of thrombin on a platelet constituent, and this is supported by other kinetic studies of the reaction (our unpublished results). This reaction requires an unsubstituted serine hydroxyl group because it is inhibited by DFP and also a group susceptible to acetylation, because acetylated thrombin, which has esterolytic but not coagulant activity, is inactive towards platelets¹⁵. A third part of the thrombin molecule is implicated by the failure of coagulase thrombin to react with platelets. This substance retains the enzymatic properties of thrombin, while differing from normally activated thrombin in physical and immunological properties12. Modification by staphylocoagulase of a site required for binding the enzyme to platelets is suggested.

It is now known that thrombin can hydrolyse peptide bonds in proteins other than fibringen 18,17. In these substrates, the peptide bonds hydrolysed are probably arginine-isoleucine, lysine-alanine or lysine-isoleucine, and not arginine-glycine as in fibrinogen. Furthermore, there is evidence that thrombin alters the activities of a number of coagulation factors8, all of which are known to be associated with platelets18. There is therefore a plethora of possible alternative substrates for thrombin. We can assume that trypsin and the similar enzymes which reproduce the effects of thrombin on platelets act on the same substrate. That a certain specificity is involved is evident from the inactivity of venom coagulants and other venom esterases, all trypsin-like in preference for synthetic substrates. Further study of this aspect may help identify the peptide bond(s) split in the reaction.

We thank Miss G. Baumlin for technical assistance. These studies were supported by the National Heart Foundation of Australia, the Kommission zur Forderung der Eiweissforschung an der Universität Bern and the Wellcome Trust.

Confirmation of the Genome Donors of Aegilops cylindrica

by

B. L. JOHNSON

Department of Agronomy, University of California, Riverside, California A method for identifying the C and D genome donors of Ae. cylindrica (CCDD) from the electrophoretic pattern of protein mixtures of Ae. caudata (CC) and Ae. squarrosa (DD) types may be useful in confirming the B genome donor of wheat.

The origin of the B genome of the tetraploid wheats (AABB) continues to be controversial. A was evidently acquired from the wild diploid $Triticum\ bocoticum\ Boiss.$ or its cultivated derivative, $T.\ monococcum\ L.$, and B presumably from a similar source or from a diploid of the related genus $Aegilops^{2-4}$. Morphological attributes on which the genome donors might be precisely identified, however, are tenuous. Furthermore, observed chromosome homology between the diploids and the tetraploids is only partial for both A and B. This lack of homology has been ascribed to differentiation of the tetraploid genomes following the incidence of amphiploidy^{2,5,6}.

Alternatively, diploid types of maximum homology with the tetraploid genomes may have failed to be identified because of the difficulty of adequately sampling the wild A and B populations by the methods of cytogenetics. This study of the tetraploid Ae. cylindrica Host. (CCDD) (Fig. 1) shows that unique C and D genome donor types can be readily distinguished in the variable population of its diploid progenitors, Ae. caudata L. (OC) and Ae. squarrosa L. (DD) by the relatively rapid method of protein electrophoresis.

Thirty accessions of the Aegilops species listed in Table 1 were increased in the field in southern California and were

documented by voucher specimens filed in the herbarium of the University of California, Riverside. Protein extracts of ground seeds made from these accessions with 70 per cent ethanol⁷ were freeze dried for prolonged storage.

Table 1. Geographical distribution and awn development in subspecies and varieties of three species of Aeqilops

,, ,, ,, ., Anathera	
., ,, ,, ., Meyeri	
, Strangulata Westward	
Ae. caudata (CC) Polyathera Eastward	
Tunian Wastward	
Ae. cylindrica (CCDD) Typica General	
., ., ., Pauciaristatu ., -	

The crude extracts were fractionated by disc electrophoresis (unpublished work of L. Ornstein and B. J. Davis) using 15 per cent acrylamide gel columns prepared with 3 molar urea and a gel formulation⁸ giving a running pH of 4·3 with β-alanine-acetic acid buffer. The sample applied to each column consisted of 0·5 mg of the dry powder dissolved in 0·1 ml. of the stacking gel solution. Optimum separation of the protein bands was obtained by electrophoresis for 2 h 15 min at 4 m.amp of current per column.

The gels were fixed and stained with 0.5 per cent annido black in 7.5 per cent acetic acid saturated with mercuric chloride, then electrophoretically destained with 7.3 per cent acetic acid and photographed. Bands in the electrophoretic patterns from different species were tested for homology (that is, equivalent migration velocity) by reference to the pattern obtained from a mixture of their proteins. The mixture pattern permitted a band by band verification of homologies between species two at a time and provided the basis for making small adjustments in the length of individual species patterns (Fig. 3) during the photographic enlargement, to compensate for small discrepancies in the speed of migration among gels in different experiments. The patterns were enlarged to conform with a standard length of 10 cm for that of Triticum dicoccum Schübl accession 497 (ref. 9).

Homologies between species were inferred mostly from the bands which had migrated -4.0 cm or farther because occasional inconsistencies of pattern can occur among the slower bands⁹.

The present range of Ae. cylindrica (CCDD) extending from the Balkan Peninsula to Sinkiang (Fig. 2) overlaps that of Ae. caudata (CC) in central Anatolia and that of Ae. squarrosa (DD) from the Transcaucasus area eastward. This suggests the upper Euphrates Tigris valley.

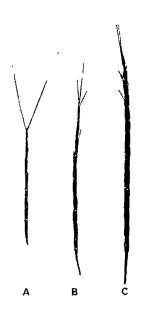

Fig. 1. Spikes of Aegilops caudata (A), Ae. cylindrica (B).
Ae. squarrosa (C).

where the diploids are not now in contact, as the probable site of origin of $Ae.\ cylindrica$. The cytological evidence of its parentage is conclusive^{10,11}, and its morphological intermediacy is apparent (Fig. 1). Early systematists¹² commented on its affinity with $Ae.\ caudata$ but not with $Ae.\ squarrosa$. A more precise identification of the C and D genome donors with recognized morphological types within the diploid species has not been attempted.

In Ae. squarrosa as in other species of the section Pachystachys Eig the lemmas are awned and the glumes unawned (Table 1). In Ae. caudata, as in other species of the section Macrathera Eig, the reverse is true. Systematically Ae. cylindrica, with less strongly developed awns on both glumes and lemmas, occupies a central position between the two. Eig¹² assigns it to the mono-

typic section Monoleptathera.

Of the three species, Ae. squarrosa is the most variable. Its subspecies eusquarrosa Eig (Table 1) comprises three varieties, typica, anathera and Meyeri. These are all generally distributed geographically but var. typica is the most common. The subspecies strangulata is a rare type occurring in the western part of the range. Lemma awn development varies from strong in var. typica to weak in var. anathera. In Ae. caudata the var. polyathera with glume awns on the lateral as well as the terminal spikelets is more common in the eastern half of the species range while var. typica with glume awns only on the terminal spikelets is more prevalent westward. In Ae. cylindrica lemma and glume awns occur throughout the spike in the common var. typica, but only at the apex of the spike in the less common var pauciaristata. Both varieties have a general distribution and transitional types occur.

All of the enumerated subspecies and varieties were represented in the electrophoretic studies except that Ae. caudata types, unequivocally referable to var. typica, were not available. Seventeen accessions of Ae. squarrosa were included from Afghanistan and Iran, six of Ae. caudata from Greece and Turkey, and seven of Ae. cylindrica from the upper Euphrates—Tigris valley and from the adjacent areas of Iran and Turkey where the tetraploid and its respective diploid progenitors intermingle. The selected gels shown in Fig. 3 illustrate the range in protein pattern observed in each species.

A characteristic electrophoretic pattern for each diploid is at once obvious. The *squarrosa* accessions (Fig. 3A-D) exhibit dense, massive bands in the faster as well as in the

slower half of the series, whereas the caudata accessions (Fig. 3E-H) show dense bands only in the slower half. All squarrosa accessions are alike with respect to a broad dense band centred at -9.7 cm which tends to fuse with a narrower one at -9.0. They all show less dense bands at -8.1, -6.7, -6.0, -5.0 cm and all have a dark leading band usually at -10.4 but exceptionally at -10.9 cm. The caudata accessions show a faint leading band at -10.4 or exceptionally at -10.6 cm. They all have discernible bands at -7.7, -6.3, -5.3, -4.2 cm, that at -5.3 being the most conspicuous.

In its general features, the *cylindrica* pattern can be visualized as a combination of the two diploid patterns. For example, it exhibits a *squarrosa* homologue at 9.7 and a *caudata* homologue at -5.3 cm. More detailed comparisons will be made after variability within the

diploid species has been considered.

The three varieties of subspecies eusquarrosa (Fig. 3A-C) can be distinguished one from another on the migration velocity of the fastest band and the degree of separation of the bands at -9.7 and -9.0 cm. Subspecies strangulata (Fig. 3D) differs from var. typica mostly with respect to the density of the bands between -3.5 and -6.0 cm. The gels illustrated in Fig. 3 were selected from ten accessions of var. typica, three of var. Meyeri, one of var. anathera and three of subspecies strangulata. Of the typica accessions six, represented by Fig. 3A, were identical except for differences in density among the slower bands, between 0 and -4.0 cm. The other four deviated towards var. Meyeri with respect to separation of the bands at -9.7 and -9.0 cm.

The six examined accessions of Ae. caudata were identified as var. polyathera. Two gave the protein pattern shown in Fig. 3E. A variation on this pattern consisted of an additional relatively dense band at -4.9 and a denser leading band at -10.4 cm (Fig. 3F). Another variation showed an extra, faint band at -5.8 cm (Fig. 3G) and a third variation showed two extra bands, at

-5.8 and -9.8 cm (Fig. 3H).

Of the three species Ae. cylindrica showed the least variability. It was represented by six accessions of var. typica (Fig. 3I-K) and one of var. pauciaristata (Fig. 3L). All of these had qualitatively identical electrophoretic patterns except possibly between 0 and -4.0 cm. The apparent discrepancy among the slower bands of var. pauciaristata is largely quantitative, because of differences in optical density. This uniformity suggests that Ae

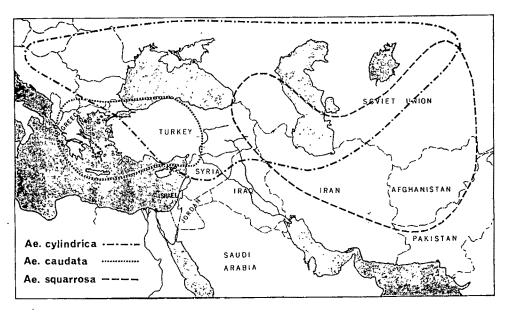

Fig. 2. Geographical distribution of Aegilops cylindrica and its putative parents, Ae. caudala and Ae. squarrosa.

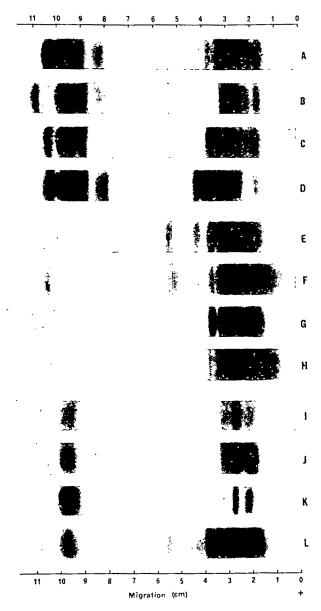

Fig. 3. Electrophoretic patterns on acrylamide gels. A, Ae. squarrosa var. typica (364). B, Ae. squarrosa var. anathera (754). C, Ae. squarrosa var. Meyeri (752). D, Ae. squarrosa subspecies strangulata (963). E-H, Ae. caudata var. polyathera (accessions 756, 592, 593, 591, respectively). I-K, Ae. cylindrica var. typica (accessions 403, 406, 401, respectively). L, Ae. cylindrica var. pauciaristata (605).

cylindrica originated with single amphiploidy event. It confirms cytogenetic evidence suggesting that neither the C nor D genome has been appreciably modified since the origin of the amphiploid. Consequently, the observed variation in the diploid patterns raises the question whether specific amphiploid progenitor types might be recovered in the populations of Ae. squarrosa and Ae. caudata. Protein mixtures from such types would be expected to duplicate the amphiploid pattern in detail.

The protein patterns of Ae. squarrosa var. typica accession 435 from Afghanistan, Ae. caudata var. polyathera accession 758 from Anatolia, and a 1:1 mixture by weight of their extracts are illustrated in Fig. 4A, B and C, respectively. These are compared with accessions 404 (Fig. 4D) and 403 (Fig. 4E) of Ae. cylindrica var. typica also from Anatolia. Except for a difference in optical density of the band at -4.3 cm and some uncertain band homologies between 0 and -4.0 cm, the mixture spectrum

is identical with that of Ae. cylindrica accession 404. Similarly, the electrophoretic pattern of accession 403 and of all the other cylindrica accessions was qualitatively essentially identical with the mixture pattern.

Similarly, any one of the six identical accessions 364, 434, 435, 436, 437, 962 of Ae. squarrosa var. typica in combination with either accession 758 or 947 of Ae. caudata var. polyathera effectively duplicated the cylindrica protein pattern. Other combinations of squarrosa and caudata accessions sufficiently promising to warrant their testing by the protein mixture method failed to do so. Variation in the cylindrica pattern was not enough to reflect any of the variation observed among other diploid accessions. Thus the enumerated accessions seem to represent unique D and C genome donor types, a conclusion which is consistent with their morphological attributes, geographical distribution and prevalence.

The ability of the protein electrophoretic method to pinpoint extant genome donor types of Ae. cylindrica in the variable populations of its diploid progenitors suggests that this technique may be useful in confirming the B genome source of the tetraploid wheats. The latter problem, obviously, is complicated by greater variability both at the tetraploid and diploid levels. At least 10 tetraploid species have been recognized. The Acgilops section Platystachys, where prevalent opinion places the B donor, comprises five species; and the A donor T. bocoticum includes at least two wild types plus cultivated

derivatives.

Diversity among the *Triticum* tetraploids may be a consequence of their postulated complex origin from primary amphiploids of different parentage¹³. Electrophoretic evidence so far^{9,14} suggests that the wild tetraploid *T. dicoccoides* Körn. may have had such a polyphyletic origin, in which case protein mixtures should be useful for identifying the various parental combinations which comprise the primary amphiploids. The primitive domesticated *T. dicoccum* Schübl with its cultivated derivatives apparently originated from one or a few dicoccoides types. The uniform protein pattern of these AABB tetraploids enhances the possibility of finding likely A and B genome donors.

The non-homology referred to between the tetraploid ${\cal B}$ genome and the genome of plausible diploid donors has

been ascribed specifically to re-arrangements of chromosome structure and mutations at the tetraploid level² and to modification of the tetraploid B genome by introgressive hybridization among various B genome types. In the first case, chromosome re-arrangements involving only the two genomes of a given tetraploid would not be expected per se to obscure gene homologies between the tetraploid and its diploid progenitor as measured by the protein pattern. Gene mutations and, in the second case, non-homology among the tetraploids generated by introgression would be expected to show new gene combinations producing protein patterns unidentifiable with an existing individual donor. But, whether such types can be expected to have subsequently predominated to the exclusion of the primary amphiploids from the population is an open question.

Proton Magnetic Resonance Studies of the Helix-Coil Transition in Polypeptides

by E. M. BRADBURY C. CRANE-ROBINSON H. W. E. RATTLE Portsmouth College of Technology, Park Road, Portsmouth, Hampshire

In proton magnetic resonance studies of polypeptides in solution, the spectral behaviour of the α -CH proton peak depends on the nature of the solvent system, the side chain and the molecular weight. It is considered a more straightforward indicator of conformation than the amide NH peak.

In a recent communication, Ferretti¹ published work on proton magnetic resonance spectra at 100 Mc/s of poly-βmethyl-L-aspartate and poly-L-leucine in trifluoroacetic acid/deuterochloroform solvent mixtures. These spectra showed that the amide NH and a-CH resonance peaks consisted of two components in solutions of partially helical polymer; one component was assigned to protons in the helical polymer and the other to protons in the random coil.

We have studied many homo- and co-polypeptides in the same solvent system and conclude that the spectral behaviour of the a-CH proton peak depends on the nature of the solvent system, the side chain and the molecular weight. Because the amide NH peak broadens more rapidly than the a-CH peak and is subject to additional rate processes, we consider the latter peak to be a more straightforward indicator of conformation. Several cases of behaviour may be defined.

(1) Helical and random coil sections interconvert rapidly; irrespective of molecular weight the α -CH peak will then be a single time-averaged resonance which remains sharp and shows an upfield shift as the helicity increases. This is seen in the spectra of poly-D-alanine shown in Fig. 1.4; the same behaviour has been noted elsewhere for this polymer²⁻⁴. The observation of single peaks for the amide NH and α -CH lines is not caused by the more limited resolution at 60 Mc/s (ref. 1) as can be seen from the 100 Mc/s spectra of several poly-D-alanine samples in 40 per cent trifluoroacetic acid/60 per cent deuterochloroform shown in Fig. 2. The poly-D-alanine samples are of different molecular weights (as judged by the reduced viscosity in dichloroacetic acid), and in 40 per cent trifluoroacetic acid/60 per cent deuterochloroform the b_0 value was about +300 for all samples. It can be seen, however, that as the molecular weight decreases some asymmetry appears in the line shapes, particularly that of the amide NH; the origin of these broader components in the poly-D-alanine spectrum is not clear.

If the helix content of poly-D-alanine is increased beyond 50 per cent by replacing trifluoroacetic acid with dichloroacetic acid, the resonance peaks broaden2. This is because of a slower interconversion rate of helical and random coil forms and the fact that, as helical segments increase in length, their correlation times become longer. The rapid interconversion rate of poly-D-alanine at helix contents as high as 50 per cent may result from the small alanine side chain and, if this is so, then the rate of interconversion for different polypeptides might be dependent on the size and nature of their side chains. For other polypeptides broadening and loss of area might therefore be expected at lower helix content. Evidence for this possibility comes from the behaviour of the a-CH resonance peaks of poly-L-leucine shown in Fig. 1B. This peak shows pronounced broadening at an appreciably lower helix content than is observed for poly-D-alanine. The single broadened peak for poly-L-leucine probably results from an intermediate interconversion rate of protons between the random coil sections and helical segments⁵.

The spectra given in Fig. 1B differ from those of Ferretti in that they do not show a double peak and this is possibly a result of differences in the molecular weight of the poly-L-leucine samples. This leads to a second type of behaviour of which Ferretti's spectra may be an example.

(2) Polypeptide chains which have a short overall correlation time, and in which the helical and random coil forms, do not interconvert rapidly. This is observed principally for low molecular weight samples and the slow interconversion rate may be a result not only of the nature of the side chain but also be a direct consequence of the short chain lengths. The short correlation time for the motion of the whole chain leads, for case (2), to two

components of comparable widths assignable to the helical and coiled forms. Examples we have studied which demonstrate this effect are given in Figs. 1C and 1D. These show the α -CH resonance of poly-D- α -amino-n-butyric acid and poly-D-norleucine in deuterochloroform/trifluoroacetic acid mixtures from 10 per cent to 40 per cent trifluoroacetic acid, a solvent range which covers a large change of b_0 values. The relative areas of these components alter in accordance with changes in helix content while the total line area remains constant. The form of these resonance peaks is very similar to those given by Ferretti¹, and, as he pointed out, the observation of the separate components puts an upper limit of $10^2~{\rm sec}^{-1}$ on the rate of interconversion between helical and coiled conformations.

The spectra given in Figs. 1C and 1D demonstrate that effects, similar to those observed by Ferretti at 100 Mc/s, can be observed at 60 Mc/s. Markley et al. have observed that the line width of the α -CH peak of poly- γ -benzyl-L-glutamate and poly-L-methionine goes through a maximum as the helix content increases. This effect was attributed to an increase in the rate of interconversion at high helix content, but it may be an example of case (2) because it can be seen from Figs. 1C and 1D that if the components were not resolved the overall line width would appear to go through a maximum when the components were of equal intensity.

(3) It is not possible in case (1) to relate the area of the backbone proton resonance peaks to the helicity because the areas remain unchanged over a large range of helix contents and in case (2) it is possible only if the two components are well resolved. There is a class of polypeptides, however, for which this correlation might be expected. These are polypeptides of high molecular weight in which the helical and random segments are either completely prevented from interconverting (for example, proteins, where the differing stabilities of helical segments could inhibit this process) or interconvert slowly either because of large side chains or because of side chains

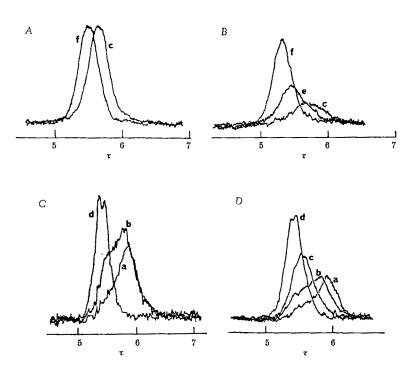

Fig. 1. The a-CH peak at 60 Mc/s of: A, poly-D-alanine; B, poly-L-leucine; C, poly-D-alanino-n-butyric acid; D, poly-D-norleucine, in the following trifuoroacetic acid/deutero-chloroform mixtures: (a) 10 per cent trifuoroacetic acid; (b) 20 per cent trifuoroacetic acid; (c) 30 per cent trifuoroacetic acid; (d) 40 per cent trifuoroacetic acid; (e) 60 per cent trifuoroacetic acid; (f) 100 per cent trifuoroacetic acid. b_0 values: Poly-D-alanine: +290 (c) +100(f); poly-L-leucine: -487 (c) -325 (e) -132 (f); poly-D-alanine: -hutyric acid: +300 (a) +100 (b) 0 (d); poly-D-norleucine: +400 (a) +314 (b) +146 (c) +72 (d).

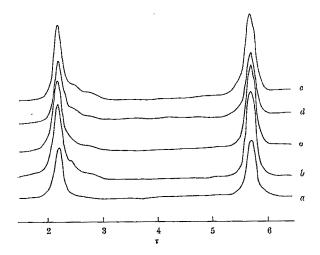

Fig. 2. The α -CH and amide NH peaks at 100 Mc/s of poly-D-alanine samples of different molecular weights. Reduced viscosities in dichloroacetic acid (l./residue mole): a,47; $b,24\cdot5$; $c,18\cdot46$; $d,8\cdot15$; e, poly-L-alanine initiated for 100-mer.

which interact strongly with the solvent. In these cases, the resonance lines from protons in helical segments will be broad and may be unobservable, while those from random coil regions will be sharp. The peak area will then be a measure of the random coil component. It is possible, however, that at low helix content the helical segments have sufficient mobility for the broad component to be observed; in these circumstances the width of the broad component would be greater than that of the narrow line. An example of case (3) for a homopoly-peptide may be the original observation of Goodman and Masudas that the ratio of the area of the amide NH peak to the terminal side chain methyl peak in poly-ethyl-L-glutamate followed the b_0 value. We have made similar

observations for poly-L-lysine-hydrobromide in aqueous solution, a system in which the side chain is not only large but also interacts with the solvent.

For proteins and polypeptides in case (3), nuclear magnetic resonance can give information on which residues are incorporated in helical segments from the behaviour of their side chain resonance peaks because the magnetic anisotropy of helical segments which have long correlation times will broaden the resonance peaks of groups close to the helical backbone. This effect has been observed for histones in aqueous solution at various salt molarities^{6,0} and for poly-γ-benzyl-L-glutamate^{4,10}.

It should be noted that cases (1) and (2) apply to polypeptides in trifluoroacetic acid/deuterochloroform: for this system the ra-CH peak shows a considerable chemical shift difference between helical and random coil forms which has been attributed to the magnetic anisotropy of the helical form as compared with the random coil form3,4. In aqueous systems, however, the shift is either much smaller as in the case of poly-Lglutamic acid4 or is absent, as we have observed for copoly (glutamic acid⁴², lysine²⁸, alanine³⁰) (ref. 7). Thus the magnetic anisotropy of the helical form is not the only factor involved in the large shift observed in trifluoroacetic acid/ deuterochloroform systems and we have suggested that an additional anisotropic effect may result from a specific interaction of trifluoroacetic acid with helical segments of the polypeptides². For aqueous systems a single α -CH peak is therefore observed and the fall-off in peak area as the helicity rises depends only on the rate of interconversion between the two conformations, unless the molecular weight is low enough for the overall correlation time to

be the line width determining factor.

It should be stressed that, because of the molecular weight dependence of some of the effects described, polypeptides used for nuclear magnetic resonance studies must be well characterized. Low molecular weight samples may explain reports that fully helical polymer gives rise to observable peaks for backbone protons, while it is our experience that fully helical polypeptides, as indicated by optical rotatory dispersion measurements, do not show these resonance peaks.

Internal Organization of the Ribosome

bу

ROSALIND I. COTTER P. McPHIE* W. B. GRATZER MRC Biophysics Research Unit, King's College, London

The conformations of RNA in yeast ribosomes and in the free state are similar. The ribosomal proteins are believed to be in the interior and associated with non-helical parts of the RNA and probably with each other; the surface is largely RNA.

Although the conformation of ribosomal RNA in solution has been studied in some detail1-5, little has been established about the organization of RNA and protein in the native ribosome. We have been concerned primarily with establishing the nature and conformation of the macromolecular components of the yeast ribosome in situ and, as far as possible, their distribution between the surface and the interior of the ribosome. We have attempted, on the basis of our results, to construct a simple model to embody the gross features of morphology which can be deduced.

Ribosomes from the yeast Saccharomyces fragilis in the exponential growth phase were prepared as previously described. They were purified by chromatography on DEAE-cellulose, and the ribosomes thus produced were stable for some hours at room temperature and for long periods in the cold. Ribosomal RNA was extracted with phenol, and ribosomal proteins were extracted with acetic acid, also described earliers. Acridine orange was purified by the procedure of Lamm and Neville⁹. Thermal difference spectra were measured with a Beckman DK-2A recording spectrophotometer and melting curves were taken from these or were measured separately in a Beckman DUinstrument. For the standardization of concentrations, $\epsilon(P)$ for the RNA was taken as 7,400 (ref. 8), and $E_{1 \text{ cm}}^{1 \%}$ for yeast ribosomes as 113 (ref. 10). Optical rotatory dispersion was measured with a Bellingham and Stanley 'Polarmatic 62' spectropolarimeter, with cells of 1 cm path in a cell housing controlled by a thermostat. Precautions were taken to avoid stray light and band width errors by ensuring that measured rotations were independent of concentration or path length and slit width.

 $\mbox{*}$ Present; address: Department of Biochemistry, Stanford University School of Medicine, California.

Sedimentation coefficients were measured with a Spinco model E ultracentrifuge, using ultraviolet absorption optics. Viscosity determinations were performed with an Ubbelohde suspended-level capillary viscometer with a water flow-rate of 5 min.

Ribosomes sedimented at 42,000 r.p.m. in the standard tris-magnesium buffer gave a single peak with sedimentation coefficient, $s_{20,w}^0 = 80.4S$. The intrinsic viscosity, obtained from extrapolation according to the Huggins equation, was 0.046 dl./g, with a Huggins constant, k'=0.65. The partial specific volume of the ribosome was taken as 0.67 (ref. 10), and the molecular weight was calculated from the Scheraga–Mandelkern equation 11, taking $\beta=2\cdot12\times10^{-6}$ for a spherical particle. We obtained a molecular weight of 3.95×10^6 .

Early attempts to measure the temperature-absorbance profiles of intact ribosomes^{12,13} produced data only up to temperatures of 40°-60° C, because of heavy precipitation in this range. We have confirmed this effect, but have also found that if the ribosomes are dissociated into their 60S and 40S sub-units by brief dialysis against a magnesium-free buffer (0·1 molar sodium chloride, 1 mmolar tris), precipitation is eliminated and complete melting profiles are obtained. A low scattering level is always observed in the ribosome solutions and correction for this was made by a logarithmic extrapolation of scattering outside the absorption band. The scattering correction at 258 mu amounted in our instrument to no more than an absorbance of 0.03 at 20° C, rising to 0.05 at 95° C, for an initial total absorbance of the order of 0.7. Fig. 1 shows temperature melting curves for the dissociated yeast ribosomes and for the extracted RNA in the same solvent. The protein absorption is assumed to remain unchanged with increasing temperature; a correction for

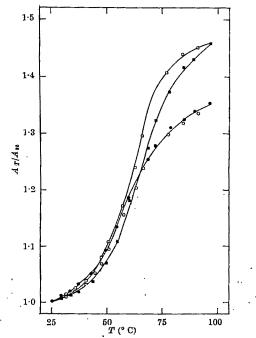

Fig. 1. Temperature-absorbance profiles of yeast ribosomal RNA and ribosomes dissociated into 60S and 40S sub-units. Absorbances of ribosomes are corrected for protein absorption. Open symbols refer to ribosomes, filled symbols to extracted RNA. $\bullet \bigcirc$, 257 m μ ; $\blacksquare \square$, 282 m μ .

the protein absorption is applied from molar absorptivities of the RNA and extracted proteins. This correction affects only the value of the absolute hyperchromic absorbance increase and not the position or shape of the curve; it is small at 260 mµ but appreciable at 282 mµ.

It can be seen, as briefly mentioned earlier 14, that at 258 m μ the melting curves of ribosomes and RNA almost coincide. At 282 m μ , where the accuracy is less (lower absorbance) and interference from protein absorption is greater, the curve for the ribosomes seems to be slightly displaced to lower temperatures. In both cases, the corrected hypochromicities are the same for RNA in the ribosome and the free state within the limits of error.

Fig. 2 shows temperature difference spectra at various temperature intervals for the ribosomal RNA. A comparison with standard difference spectra for poly $(A+U)^{16}$ and poly $(G+C)^{16}$ shows (as do the curves of Fig. 1) that the regions melting out as the temperature increases become progressively richer in (G+C) content. The top curve of Fig. 2 gives the composition of the total RNA helix in terms of these standards and within limitations to be discussed as about equimolar in the four bases.

The interaction of acridine orange with ribosomal RNA, extracted protein and intact ribosomes has been studied. The dye binds to ribosomes as workers previously noted 17,18 but not at all to proteins. Fig. 3 shows spectrophotometric titrations of acridine orange with ribosomes and extracted proteins. Determination of the number of sites available to the dye in the intact ribosomes presents considerable difficulties. To maintain the integrity of the structure an appreciable concentration of magnesium ions is required and magnesium greatly weakens the affinity of the binding sites for the dye (presumably by competition). Consequently, titrations of dye with ribosomes or RNA in these conditions show curvature (as theoretically predictable19) which precludes the accurate determination of end In the conditions used by Furano et al.18, especially with the more magnesium-dependent ribosomes from E. coli, the structure must be presumed to be wholly or partly disrupted20,21 and we therefore suppose that in such conditions a limiting value is obtained for the number of binding sites. The situation is further complicated by the possibility that the curvature of the binding isotherms may be due, at least partly, to a heterogeneity of the binding sites, rather than to weak binding alone. Such an effect has indeed been suggested for binding of acridine dyes on DNA^{22,23}. Our value of about 90 per cent (Fig. 3) for the proportion of phosphate sites available must thus be seen as an upper limit as far as the intact ribosome is concerned. It is in good agreement with that of Furano et al.18 for E. coli ribosomes and qualitatively similar to the result of Morgan and Rhoads¹⁷. If one takes the curvature to reflect heterogeneity of binding, an end point corresponding to as little as 60 per cent of the total phosphate groups can be derived. We have made one further attempt to overcome this problem: it has been shown²⁴ that ribosomes can be internally cross-linked by formaldehyde and will then maintain their native morphology even in the absence of magnesium. Ribosomes treated as described by Spirin et al.24 were indeed shown to sediment at 80S, even in the presence of EDTA. The accidine orange binding curve (Fig. 3) shows the availability of about 80 per cent of the phosphates. We therefore take this as an effective upper limit. It may be noted that ribosomes saturated with dye remain intact, and sediment in the ultracentrifuge as an orange boundary.

Fig. 2 shows that the helical portion of extracted yeast ribosomal RNA is made up of a heterogeneous population of helices of varying composition which melt over a wide temperature range. On the basis of data for synthetic polynucleotides^{15,18}, the total helix content is estimated to be about 60 per cent. This is probably a lower limit, as the full hypochromicity of short helices does not seem to be realized until a substantial helix length has been reached^{25,26}. It is also assumed that the hypochromicity arises entirely from Watson-Crick double helices, and no

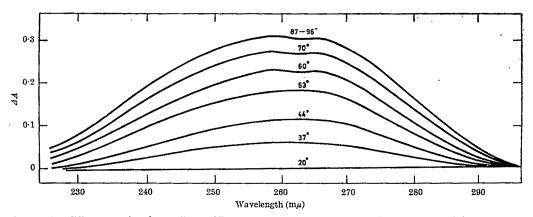

Fig. 2. Temperature difference spectra of yeast ribosomal RNA. The curves show absorbance differences (uncorrected for thermal expansion) of RNA at the indicated temperature. RNA at 20° C is used as reference.

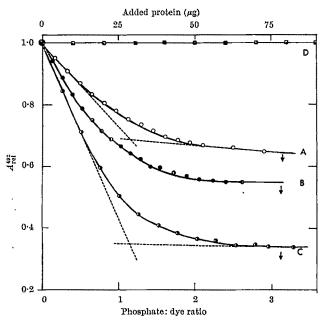

Fig. 3. Spectrophotometric titrations of aeridine orange with yeast ribosomes and extracted soluble ribosomal proteins. A. Ribosomes in the presence of 1 mmole magnesium ion; B, ribosomes in 2 mmoles magnesium; C, ribosomes treated with formaldehyde, no magnesium ions; D, extracted ribosomal proteins. account is taken of any single strand stacked structures^{27,28}, although some such structure must in fact be present.

We can deduce little, quantitatively, about the lengths of helical regions, although a minimum length can be tentatively set in terms of data on oligomer-polymer complexes^{28,31}. At the same time, a comparison of the temperature absorbance profiles of Fig. 1 with those of two stranded viral RNA^{32,33} shows that the helices in ribosomal RNA are not "long". Taking into consideration the formation of crystalline helical fragments with average chain lengths of about forty nucleotides*, by controlled degradation of yeast ribosomes³⁴ and ribosomal RNA (Spencer et al., to be published), we conclude that the helical portions in the native state are unlikely to be longer than this. The assumption that ribosomal RNA is made up of rod-like double helical "hairpin" segments, joined by single stranded links¹⁻⁵, seems then to be entirely compatible with our results on the yeast system.

Fig. 1 also suggests that the conformation of the RNA in the ribosome is similar to that of free RNA, and indeed the value of the hypochromicity of the ribosome seems to bear this out further (compare similar evidence from hypochromicity in *E. coli* ribosomes³⁸). This conclusion conflicts with that of Furano et al. 18, based on measurements of stacking coefficients for binding of acridine orange to *E. coli* ribosomes at low magnesium concentrations. The stacking coefficient 39,40 is a measure of the tendency of an incoming dye molecule to bind at a site adjacent to one already occupied by another dye molecule. Nonrandom binding in these terms is thought to depend on the flexibility of the polymer chain, the stacking coefficient

being high for polynucleotides possessing little or no base pairing. From the values of their stacking coefficient for the ribosome-dye interaction, Furano et al. conclude that ribosomal RNA in the ribosome has a conformation quite different from that in the free state and is in fact single stranded, with no base pairing.

To account for this apparent discrepancy in our results, we offer the following arguments. (1) The interpretation of stacking coefficients in terms of conformation implies that the polynucleotide chain is flexible in the ribosome and can freely distort to allow stacking of the dye molecules. If the ribosome is a rigid structure, then such a deformation would presumably be impossible and the magnitude of the stacking coefficient would then be uninterpretable. (2) The close similarity of the optical rotatory dispersion curves of RNA in the free state and in the ribosome (correction being made for the protein contribution) has been noted by several groups of This suggests that the conformations are in fact similar. If the RNA were single stranded, a different curve would be expected. Fig. 4 shows some results: ORD curves for single stranded ribosomal RNA, based on the dinucleotide data, as applied by Cantor et al.43, have been computed. The curve in Fig. 4, corresponding to a random sequence of the correct base composition, is shown to be very different from the observed curve. By working at very low ionic strength, the RNA may in fact be obtained in the fully single stranded form (compare TMV RNA43). The ORD curve of this form is shown in Fig. 4, and is seen to be in agreement with the calculated curve (based on pairwise interaction of nucleotides). On addition of salt, a large change occurs, the curve moving in the direction predicted for the introduction of substantial base pairing. The introduction of base pairing into a calculation requires more drastic approximations and is less quantitatively reliable. Even here, however, the experimental curve is seen to be quite close to the theoretical, and, for the composition of the double helical portion deduced from our thermal difference

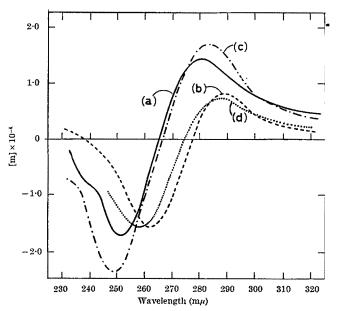

Fig. 4. Calculated and observed optical rotatory dispersion curves for yeast ribosomal RNA. (a) Observed curve for yeast ribosomal RNA (ionic strength 0·1); (b) observed curve for ribosomal RNA in 10·4 molar EDTA (no other salts present); (c) calculated ORD curve for 60 per cent base pairing. The composition of the base paired part was derived from thermal difference spectra. The curve was calculated using standard dinucleotide data⁴³ for the unpaired part, assuming a random sequence of the appropriate base composition, and data for the double-stranded part were obtained directly from Sarkar and Yang^{56,58} for poly (A+U) and poly (G+C). (The difference curves of Cantor et al.⁴³ do not give the correct result for such a system, because they are based implicitly on single strand states of homopolymers.) (d) Calculated ORD curve for a single stranded chain with the base composition of ribosomal RNA, assuming a random sequence.

^{*} The fragments used for the X-ray studies 36,36 have been characterized hydrodynamically (Gratzer, unpublished work) with the following results: partial specific volume 0·506 (determined by the sinker method), $s^0_{20,w} = 2\cdot5S$, intrinsic viscosity 0·050 dl./g, extrapolated weight–average molecular weight (corrected for charge effects) from sedimentation equilibrium 14,800, z-average molecular weight about 21,000. This gives $M_z/M_w \sim 1.4$. The sample was found by acrylamide gel electrophoresis to contain some 12 per cent sRNA. Taking this into account it appears that the fragments which can be crystalized have $M_w \sim 13,000$, and a weight–average length of some forty nucleotides, athough, as hypochromicity and optical rotatory dispersion studies indicate, a considerable amount of non-crystalline amorphous material is present.

spectra, our estimate of 60 per cent base pairing produces the best fit. From these results we are prompted to argue strongly against a single stranded conformation in the ribosome. (3) Finally, we may mention that when acridine orange is bound to RNA it becomes optically active with Cotton effects in the visible region. These are strongly dependent on conformation and can even have different signs in different polynucleotides. We have examined complexes with RNA and ribosomes at saturation and find Cotton effects of identical shape, although the amplitude in the ribosome complex is somewhat greater. We shall therefore proceed on the assumption that our picture of RNA conformation is valid in relation to the ribosome.

The close coincidence of the melting curves of RNA and ribosomes (Fig. 1) leads to a further important conclusion. It is well known that when a basic polymer, such as a ribosomal protein, binds to a nucleic acid, the double helical state of the latter is strongly stabilized, and the melting temperature is raised by some 15°-20° C at ionic strengths such as those used here44-46. Indeed, Bach and Miller46 have shown that substantial increases in melting temperature are brought about by binding of polyampholytes containing only a minimal or zero excess of basic over acidic groups. The absence of any substantial stabilization effect in Fig. 1 can be interpreted only as indicating that the protein is not bound to the helical

regions of the RNA.

The weight-average molecular weight of the yeast ribosomal proteins has been given as about 15,00010 and these proteins, which are partly a-helical and evidently globular in character in situ8, will have an average diameter, based on their partial specific volume of the order of 30 Å. Such a sphere could be accommodated, taking the extreme case, in a loop of RNA a minimum of some 50 Å long (half the circumference of the sphere), which would correspond to some seven nucleotides if the chain were fully extended (taking 7.2 Å as the repeat distance for a fully extended polynucleotide chain). Because the yeast ribosome contains 57 per cent by weight of protein^{10,47}, that is, about 150 molecules, the total minimum length of loop corresponds to somewhat more than one thousand nucleotides but is likely to be substantially greater. On the basis of 5,400 nucleotides in the ribosome, it follows that the greater part of the non-helical nucleotides (more in any case than a minimum of one-half of the minimum non-helical proportion of 40 per cent) would be involved in fixation of the proteins. A possibility which may be considered is that the proteins may be to some extent associated with each other, as in typical sub-unit situations. The total protein-RNA contacts in such a situation and thus the proportion of RNA involved would be considerably diminished. This picture receives some support from the high degree of association between the extracted proteins48.

The temperature-absorbance profiles at 282 m μ (corresponding chiefly to the melting of G-C pairs) actually show a small apparent destabilization of the RNA in the ribosome. The readings at this wavelength are, however, smaller and subject to a considerable correction for protein absorption, which probably changes slightly itself in accordance with the familiar denaturation blue-shift phenomenon48 and we are therefore disinclined to regard this small effect as significant*.

The dye binding experiments indicate that a large proportion of the RNA is available on the surface of the ribosome. We cannot rule out the possibility that the dye penetrates the ribosome and binds in its interior, but it seems inconceivable that anything approaching such a large number of dye molecules could enter the structure. Furano et al.18 argue from their observation that, as acridine orange can be displaced from the ribosomes by high molecular weight polylysine, it must be on the

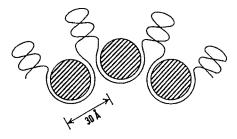

outside. It should be noted that basic polymers, such as this and the ribosomal proteins, must compete with the acridine orange for RNA sites, so that, if the protein is at the centre and shielded, unfolding of the structure will not necessarily expose any large number of unoccupied binding sites. If, however, the protein were on the surface, it would either be displaced by the dye, or the dye-binding capacity would be very small indeed. We have shown that in fact no significant amount of protein is displaced by acridine orange: dye-ribosome complexes of widely varying compositions were pelleted in the ultracentrifuge, and protein in the supernatant was assayed by hydrolysis and spectrophotometric ninhydrin determination⁵¹. An upper limit of about 5 per cent of the total ribosomal protein only can be displaced by the dye.

The conclusion thus seems almost inescapable that the exterior of the ribosome consists substantially of RNA rather than protein. If, moreover, it is accepted that the proteins are associated with the non-helical, rather than helical segments, the exposed RNA should be essentially helical. This is supported by the remarkable resistance of the intact ribosome to ribonuclease52.

Electron microscope examination of yeast ribosomes¹⁰ shows roughly spherical particles with a radius of about 100 Å. The hydrodynamic properties, however, indicate that the effective hydrated particle in solution is larger. The partial specific volume (anhydrous) leads to a volume of 4.3 × 104 Å3, and a radius for a spherical particle of 100 Å; this coincides with the electron microscope value, and suggests that the desiccated particle thus observed is in its most compact state. The frictional coefficient calculated from our sedimentation data is 2.7×10^{-7} and the corresponding frictional ratio is 1.41. For a spherical particle, this leads to a hydrodynamic radius of 140 Å. (Effective hydration 1.2 g/g; it cannot be determined to what extent this hydration represents an external hydration shell, rather than a swollen particle.)

We are now able to construct a tentative model of the yeast ribosome. The surface of the dry particle can accommodate a maximum of 3,400 helical nucleotides. if the helices lie closely packed on the surface. accounts for total number of helical nucleotides deduced to be present. In the hydrated, swollen, particle these helices would presumably be less closely packed. Alternatively, one may consider the RNA helices to project from the surface, as shown in Fig. 5. In this case, the surface area is sufficient to accommodate very easily a sufficient number of helices, no matter how short the average helix. In this model, the accessibility of all helical sites to the dye molecules becomes less problematical. In either case. the amorphous loops are envisaged as projecting into the centre of the ribosome, where they are interleaved with protein molecules. The simple model of Fig. 5 seems to satisfy all the observations. Its relation to the surface patterns observed in electron micrographs of shadowed E. coli ribosomes⁵³ is not obvious, although no incompatibility necessarily exists. Indeed, the lattice of crystal-

INTERIOR

Fig. 5. Suggested model (schematic) of ribosome structure. The diagram shows part of an idealized section of a yeast ribosome, the proteins being shown as shaded spheres attached to the non-helical parts of the RNA in the interior of the particle.

^{*} A recent report of melting curves of intact $E.\ coli$ ribosomes shows the presence of a small phase of lower melting temperature. We have not observed this effect in yeast ribosomes under our conditions.

line RNA 36 does show a periodicity of 40 Å, which is similar to the surface period observed by Hart; a 45 Å X-ray reflexion has also been reported in ribosome gels⁵⁴.

Our principal tentative conclusions then are: (a) the conformation of the RNA in the ribosome is similar to that in the free state, and contains about 60 per cent of paired bases in short helical segments; (b) the proteins are not associated with the double helical parts of the RNA, and may be packed into the non-helical loops and/or associated with each other in some form of quaternary structure; (c) the surface of the ribosome consists chiefly of RNA and not protein; and (d) this surface RNA is, by inference, largely double helical, and the helices probably project outwards from the surface.

We thank Drs D. F. Bradley, M. Spencer, E. G. Richards and H. Simpkins for discussion, advice and criticism, and Sir John Randall and Professor M. H. F. Wilkins for support and interest. R.I.C. and P.M. acknowledge support from Medical Research Council training scholarships.

Prostaglandins: Their Disappearance from and Release into the Circulation

by . S. H. FERREIRA* J. R. VANE

Department of Pharmacology, Institute of Basic Medical Sciences, Royal College of Surgeons of England, Prostaglandins are released into the splenic venous blood when the spleen contracts. Whatever the significance of this release, the liver and lungs provide an efficient protective mechanism to remove almost all the prostaglandin before it reaches the arterial circulation.

Prostaglandins are widely distributed in animal tissues and are found in particularly high concentrations in seminal fluid. They have potent actions on smooth muscle, including contraction of intestinal muscle and vasodilatation. More than a dozen different prostaglandins have been identified, and recent experiments suggest that some may be released into the circulating blood. For example, stimulation of perfused adrenal glands with acetylcholine liberates a prostaglandin², and stimulation of the splenic nerve in the dog causes large amounts of prostaglandin E_2 to be released into the splenic venous blood. The actions of prostaglandins on the arterial resistance vessels. make it important to know whether a

* Present address: Department of Pharmacology, Faculdade de Medicina de Ribeirão Preto, São Paulo, Brazil.

prostaglandin released into the venous side of the circulation is able to reach the arterial side in effective concentrations.

Methods of assaying prostaglandins have until now depended on their purification by selective extraction procedures followed by bioassay, usually on strips of isolated intestinal smooth muscle such as the rabbit jejunum, the hamster or rat colon or the rat stomach strip. We have used the blood-bathed organ technique, to estimate continuously the concentrations of prostaglandin in the circulation, to determine their stability in the blood and their disappearance in different vascular beds. The release of prostaglandin into splenic venous blood after splenic nerve stimulation, or after injections of catecholamines, has been demonstrated with the same technique.

Animals of either sex were used. Cats weighing 2-4 kg were anaesthetized with ethyl chloride and ether from a mask; anaesthesia was then maintained with chloralose (80 mg/kg given intravenously). Dogs weighing 5-15 kg were anaesthetized with halothane delivered from a Goldman vaporizer; anaesthesia was then maintained with chloralose (100 mg/kg given intravenously) and supplemented when necessary with pentobarbitone (5-10 mg/kg, given either intramuscularly or intravenously). Rabbits weighing 2-5 kg were anaesthetized by injecting pentobarbitone (20-40 mg/kg) into a marginal ear vein. The anaesthesia was supplemented when necessary by further doses (5-10 mg/kg) given intramuscularly.

In each experiment, the trachea was cannulated and the lungs were ventilated mechanically. Polyethylene cannulae were tied into a femoral or carotid artery and a femoral or jugular vein for removal and replacement of blood. Mean arterial blood pressure was recorded on a Beckman Offner 8' channel dynograph with a Statham P23 Db pressure transducer attached to the side arm of the arterial cannula. Heparin (1,000 IU/kg) was injected intravenously and the assay organs were then superiused with blood delivered by a roller pump at 10 ml./min. After passing over the assay organs, the blood collected in a reservoir and was returned to the venous cannula. either by gravity or by a second channel in the roller pump.

Three strips of intestinal smooth muscle were used as assay organs. They were suspended in polypropylene chambers and superfuseds in series, first with Krebs solution while the animal was being prepared, and then with blood from the animal. The movements of the smooth muscles were detected with 'Ether' strain gauges attached to auxotonic levers9 and recorded on the dynograph. The initial load on the tissues was 1-3 g. The assay system was calibrated by infusions of prostaglandins into the stream of blood after it had left the animal, and

by intravenous or intra-arterial infusions.

Choice of Assay Organs

The rat stomach strip¹⁰ which is contracted by prostaglandins was used for their quantitative estimation in blood. The strip is also contracted by other substances, such as 5-hydroxytryptamine, which may be present in blood. Specificity was increased by the inclusion of other tissues in the assay system. Several different isolated organs were tried; the best combination was found to be a rat stomach strip with a rat colon¹¹ and a chicken rectum¹². All these three isolated organs contracted to low concentrations (1-10 ng/ml.) of prostaglandins; no other substance in concentrations likely to be found in the blood stream gave a similar pattern of contractions.

Part of an experiment, in which a rat stomach strip, a rat colon and a chicken rectum were bathed in blood from a dog, is shown in Fig. 1. The contractions of the assay tissues produced by prostaglandin E_1 were compared with the effects induced by slow reacting substance in anaphylaxis (SRS-A), substance P, angiotensin, histamine, oxytocin and vasopressin. A pattern of contractions, similar to that produced by prostaglandin E_1 , was produced only by vasopressin but with a concentration many times higher than that found in blood. Bradykinin and 5-hydroxytryptamine gave different patterns, inducing large contractions of the rat stomach strip with little or no effect on the rat colon and chicken rectum¹³. In all

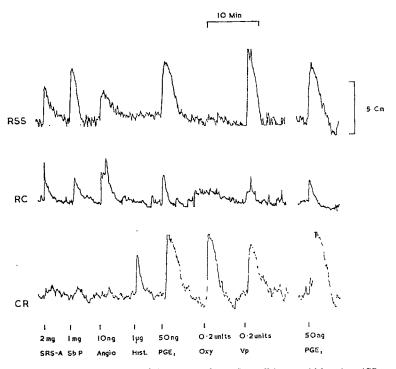

Fig. 1. A rat stomach strip (RSS, top), a rat colon (RC, middle) and a chick rectum (CR, bottom) were superfused with blood from a dog. Injections were made into the blood bathing the assay organs. Slow reacting substance in anaphylaxis (2 mg SRS-A), substance P (1 mg SbP) and angiotensin (10 ng Angio) had no effect on CR but contracted RSS and RC. Prostaglandin E_1 (50 ng PGE₁) contracted all three tissues, oxytocin (0.2 units oxy) contracted only the CR and vasopressin (0.2 units Vp) contracted all three. The dose of vasopressin to produce this effect was, however, much greater than would usually be found in blood. Time, 10 min; vertical scale, 5 cm.

experiments to be described these three blood-bathed organs were used to assay prostaglandins.

Stability of Prostaglandins in Blood

The stability of prostaglandins was measured in blood by passing it through a length of silicone tubing of 3 mm internal bore and of 30 ml. capacity, kept at 37° C by a water bath. The blood from this incubating circuit¹⁴ was then superfused over the assay organs. Prostaglandins were infused at different points in the circuit, so that they were incubated with the blood for various times before being assayed. Fig. 2 shows sections of tracings from an experiment on a dog in which the effects of infusions of prostaglandins E_1 , $\bar{E_2}$ and $F_{2\alpha}$ into the incubating circuit were compared with those produced by infusions close to the assay tissues. None of the three prostaglandins lost activity when incubated with the blood for 2 min. Similar results were obtained in three other experiments on dogs. It was not possible to use such a large incubating circuit in cats because too much blood would have been needed to fill the external tubing; nevertheless, there was no loss of activity when the three prostaglandins were incubated with cat blood for 1 min (Table 1). The finding15 that bovine plasma albumin completely suppressed the contractor activity of irin (which contains a mixture of prostaglandins 18) on isolated smooth muscle suggested that prostaglandins were bound to some plasma protein. Our results show either that this does not happen in the dog and cat or that, if it does, the resultant complex is still pharmacologically active.

Disappearance of Prostaglandins during one Circulation through Vascular Beds

When a prostaglandin is infused into the blood supplying a vascular bed, some of it disappears from the blood and the rest escapes into the venous effluent and mixes with other venous blood. The prostaglandin which escapes can be assayed by comparing the contractions of the assay

	$1\overline{2}$	Cat	E_1 (2 $\mu g/min$)	66

The figures in parentheses indicate the blood concentration for the incubation experiments and the rate of infusion into the effluent blood for the experiments in which comparisons were made across different vascular beds

organs bathed in mixed venous blood with those produced by infusions made directly into the blood leaving the vascular bed. In our experiments, sufficient time was allowed for equilibrium conditions to be established, as shown by the contraction of the assay organs reaching a plateau. The disappearance of prostaglandins was measured in the lungs, the liver and the hindquarters.

To study the disappearance of prostaglandins in the lungs, a catheter was inserted retrogradely through the right carotid artery so that its tip lay in the left ventricle, as determined by the pulse pressure registered by a pressure transducer. The tip was then withdrawn until the change in pulse pressure showed that it lay in the ascending acrta just above the acrtic valves. The position of the catheter was verified at the end of the experiment.

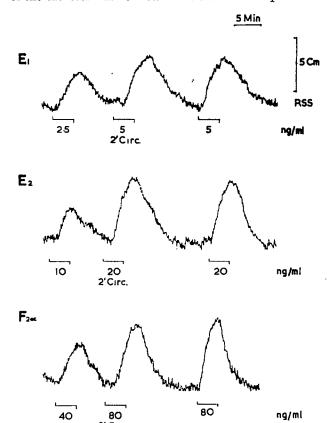

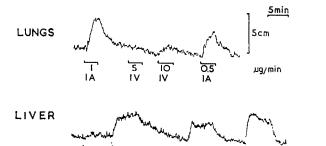

Fig. 2. Each section of tracing is from a different experiment in which a rat stomach strip was superfused with blood from a dog. The first tracing shows that incubation of prostaglandin E_1 (5 ng/ml.) for 2 min with blood did not reduce its activity. The other two tracings show similar results with prostaglandin E_2 and $F_{2\alpha}$. Time, 5 min; vertical scale, 5 cm.

5

ΙP

10

Fig. 3. The top tracing is of a rat stomach strip superfused with arterial blood from a cat. Infusions of prostaglandin E_2 (1 μg and 0.5 $\mu g/min$) were given into the ascending aorta (IA) and their effects compared with intravenous infusions (IV) of 5 and 10 $\mu g/min$. None of the 5 $\mu g/min$ intravenous Infusion could be detected in arterial blood and less than 0.5 $\mu g/min$ after the 10 $\mu g/min$. The pulmonary circulation therefore removed more than 95 per cent of the intravenous infusion. The lower tracing is from an experiment in another cat in which the rat stomach strip was bathed in mixed venous blood and infusions of PGE₂ made either intravenously or into the portal vein (IP). From an infusion of 10 $\mu g/min$ IP, more than 1 μg and less than 2 $\mu g/min$ were detected in the venous blood. Time, 5 min; vertical scale, 5 cm.

Infusions of prostaglandins were made either through this catheter (intra-arterially) or into the superior vena cava (intravenously). Thus, by comparing the effects of these infusions on assay organs bathed in femoral arterial blood, the disappearance of prostaglandins in the pulmonary circulation could be estimated. The results of an experiment in a cat are illustrated in Fig. 3. Infusions of prostaglandin E2 (0.5 µg and 1 µg/min) intra-arterially gave graded contractions of the rat stomach strip. In between these two, intravenous infusions were given. No prostaglandin was detected in the arterial blood after 5 µg/min intravenously and less than 0.5 μg/min after the intravenous infusion of 10 μg/min. Thus more than 95 per cent of the infused prostaglandin was removed in one circulation through the pulmonary vascular bed. similar result (>95 per cent removal) was obtained in another cat. With these rates of infusion, there was no change of blood pressure. In two other species (rabbit, two experiments; dog, one experiment), the disappearance of E_1 in the pulmonary circulation was found to be 90 per cent in each experiment. Thus in all three species, the lungs removed almost all of the infused prostaglandins presented to them. The results are summarized in Table 1.

To study the liver, the abdomen was opened and the spleen removed. A catheter was inserted into the splenic vein and advanced so that its tip lay in the portal vein close to the liver. The assay organs were bathed in mixed venous blood taken from the right atrium and infusions of prostaglandin into the portal circulation were compared for their effects on the assay organs with infusions into the superior vena cava. In one experiment in a cat (Fig. 3), an infusion of 10 μ g/min prostaglandin E_2 into the portal circulation gave a contraction of the rat stomach strip which was intermediate to those produced by intravenous infusions of 1 µg/min and 2 µg/min. Thus 70 per cent of the infused prostaglandin disappeared in one passage through the portal circulation. In another cat, 93 per cent of the prostaglandin disappeared in the portal circulation (Table 1).

For the hindquarters, a catheter was inserted retrogradely through a ligated femoral artery so that its tip lay just above the bifurcation of the aorta. The venous catheter was introduced into the femoral vein on the same side. Mixed venous blood taken from the right atrium was used for assay. In one cat, 50 per cent of prostaglandin E_1 disappeared in the hindquarters and, in another, 66 per cent of prostaglandin E_2 (Table 1).

We can conclude that although the prostaglandins we have tested are stable in circulating blood, they are rapidly removed from the circulation by the liver, the lungs

and to a lesser extent by the hindquarters. Should one of them be released into the portal blood, for example, from the intestine, more than 70 per cent will be removed in the liver and, of that which is left to reach the lungs, more than 90 per cent will be removed. Thus, in the few seconds that it takes for portal blood to reach the aorta, the concentration of prostaglandin in it will be reduced to less than 1 per cent. Because splenic contraction (see later) leads to prostaglandins being released into the portal vein, the avid removal of these substances by the liver and lungs may be an important protective mechanism to prevent them from reaching the arterial circulation. In the ewe¹⁷ as well as in dogs18, cats and rabbits, the hypotensive effects of prostaglandins are greater with intra-arterial than with intravenous injections; thus the mechanism for removing prostaglandins in the pulmonary circulation exists in several species. In this context, it is interesting that after administration to rats19 and mice20 of prostaglandin E_1 labelled with tritium the radioactivity was found mostly in the lungs and that lungs from many species have an enzymatic system which metabolizes prostaglandins21,22.

In our experiments, we have used infusions of prostaglandins, rather than injections, in an attempt to mimic possible release of prostaglandins into the circulation. Because intravenous injections of prostaglandins have pronounced cardio-vascular effects, it may be that the high concentration achieved by a sudden injection swamps the inactivation mechanism in the lungs, thereby allowing passage of a greater proportion of an injection than of an infusion.

Release of Prostaglandin-like Substance from the Spleen

The abdomen of the anaesthetized dog was opened down the mid-line. The vessels connecting the spleen to the stomach were tied and the spleen was freed from mesenteric tissue so that it could be exteriorized. The vascular pedicle was carefully dissected to separate lengths of splenic vein and artery from the sheath of splenic nerves surrounding the artery. A catheter was made from polyethylene tubing of 3-5 mm external diameter with one end doubled around on itself for a length of about 2 cm. This was tied into the splenic vein so that the catheter drained the splenic venous blood. After cannulation, which usually took 15-30 sec, the catheter was allowed to empty into the venous reservoir through which the blood from the assay organs returned to the animal. The assay organs were then bathed in splenic venous blood taken at 10 ml./min from a side arm in the catheter, the surplus effluent from the spleen draining into the venous reservoir. Electrodes were placed on the sheath of splenic nerves and the whole organ was then inserted into an oncometer, the volume changes of which were detected by a Palmer float recorder. Changes in spleen volume were recorded on the dynograph by attaching an 'Ether' strain gauge to the pivot of the float recorder, so that the strain gauge transduced the movements of the float recorder.

In some experiments, splenic venous blood was pumped over two separate banks of assay organs, allowing registration of the responses of six assay organs. In a few experiments, a fine polyethylene catheter was pushed into one of the ligatured tributaries of the splenic artery so that its tip lay in the main splenic artery. This catheter was used for intra-arterial injections to the spleen.

Part of an experiment, in which six assay organs were bathed in splenic venous blood, is shown in Fig. 4. Stimulation of the splenic nerve at 30 shocks per min for 2 min (1 msec duration, 30 V strength) led to a small contraction of the spleen and this was followed by an output of a material into the splenic venous blood which contracted the rat stomach strips. A higher rate of splenic nerve stimulation (1 shock per sec for 2 min) gave a larger contraction of the spleen, followed by a contraction of all the assay organs. With stimulation at 2 shocks per sec for 2 min there was an even greater contraction of the spleen

and of the assay organs. The effects of the released substance on the assay organs could be almost matched by infusing prostaglandin E_2 into the splenic venous blood to give a concentration of 30 ng/ml. The pattern of contraction of the assay organs indicated that the released material resembled prostaglandin. The lack of exact correspondence between the contractions of the individual organs induced by the material and those induced by prostaglandin E_2 may have resulted from the release of more than one prostaglandin, or from the concomitant release of a catecholamine which, by an inhibitory effect on some of the assay organs, may have changed their heights of contraction in relation to the others.

This experiment showed that when the splenic nerve was stimulated, a prostaglandin-like material was liberated in high concentrations into the splenic venous blood, confirming the work of Davies, Horton and Witherington³. Furthermore, the output of the prostaglandin-like activity depended on the frequency of nerve stimulation (five experiments). Whenever the splenic nerve was stimulated sufficiently strongly to induce a contraction of the spleen there was a release of prostaglandin-like activity into the splenic venous blood.

Identification of Prostaglandin-like Material

Samples of splenic venous blood obtained before, during and after splenic nerve stimulation were kindly extracted

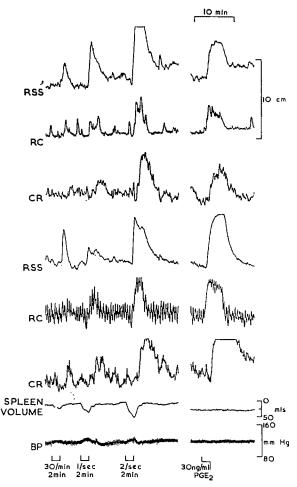

Fig. 4. Splenic venous effluent was superfused over two banks of assay organs (10 ml./min for each channel). Stimulation of the splenic nerves at 30 shocks per min for 2 min caused a small contraction of the spleen which was followed by an output of a material in the venous blood which contracted the rat stomach strips (RSS). Stimulation at 1 shock per sec for 2 min induced a bigger contraction of the spleen and a contraction of all the assay tissues. Stimulation at 2 shocks per sec for 2 min induced a still bigger effect on spleen volume and on the assay organs. An infusion of prostaglandin E₂ to give a blood concentration of 30 ng/ml. induced a similar contraction of the assay organs. Time, 10 min: vertical scales, 10 cm, change in spleen volume (ml.) and mm mercury.

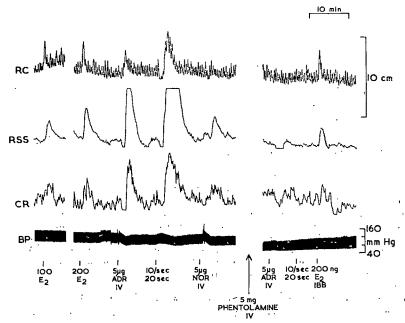

Fig. 5. A rat colon (RC, top), a rat stomach strip (RSS, upper middle) and a chick rectum (CR, lower middle) were superfused with splenic venous blood from a 12.5 kg dog. The blood pressure is the bottom tracing. Prostaglandin E_2 (100 ng and 200 ng E_2) contracted the assay organs when injected directly into the blood bathing them. An intravenous injection of adrenaline (δ μ g ADR IV) produced an output of prostaglandin into the splenic venous blood, as did stimulation of the splenic nerves at 10 shocks per sec for 20 sec. The output after intravenous noradrenaline (δ μ g NOR IV) was much smaller. Phentolamine (δ mg IV) was then given and, 20 min later, neither the adrenaline injection nor the nerve stimulation induced prostaglandin release. Time, 10 mln; vertical scales, 10 cm and mm mercury.

and assayed for us by Dr J. H. Wyllie. The blood was centrifuged and the plasma was acidified by adding one twentieth of its volume of 5.75 normal hydrochloric acid. The acidified plasma was extracted twice with 1.5 times its volume of ethyl acetate. This extraction procedure eliminates all other substances known to contract the rat stomach strip leaving only acidic lipids; it gives an 80–90 per cent recovery of added prostaglandin from blood. The ethyl acetate was evaporated to dryness; the residue was extracted with Krebs solution and its activity assayed on the rat stomach strip.

In three experiments in which the assay by this method was compared with assay by the blood bathed organ technique, there was always an increase in the prostaglandin content of the blood after splenic nerve stimulation as measured by both methods. The concentrations varied from 10-200 ng/ml. when assayed as prostaglandin E_2 , and are similar to those obtained by Davies, Horton and Witherington³, who identified the chief component as prostaglandin E_2 . For the rest of this article, we shall assume that the material in splenic venous blood which contracts the blood bathed organs is principally if not all prostaglandin E_2 .

is principally, if not all, prostaglandin E_2 . The prostaglandin E_2 may have been released from nervous tissue on excitation, from the smooth muscle of the spleen as it contracted, or it may have been present in the blood ejected from the splenic sinusoids by the contraction. To test whether the prostaglandin came from the nerve or was consequent on contraction of the spleen, drugs which cause splenic contraction were injected intra-arterially. Adrenaline (four experiments) was the most potent, followed by noradrenaline (two experiments) and histamine (three experiments). They all induced con-

tractions of the spleen which were closely followed by release of prostaglandin into the splenic venous blood. The output of prostaglandin was greater when the contraction of the spleen was greater. Thus the prostaglandin which is released follows contraction of the spleen and not excitation of nervous tissue per se.

The release of prostaglandin E_2 induced by nerve stimulation is abolished by phenoxybenzamine3, an α-receptor blocking agent. We have confirmed this observation using a different α-receptor blocking agent, and in addition have shown that the output of prostaglandin produced by adrenaline and noradrenaline is also prevented in the presence of α-blockade. Fig. 5 shows contractions of the assay organs induced by prostaglandin E_2 (100 ng and 200 ng) given directly into the splenic venous blood bathing the assay organs. Next, adrenaline (5 μ g) was injected intravenously into the dog. After a small relaxation of the assay organs, presumably because some of the adrenaline reached them, there was a contraction caused by prostaglandin release. Stimulation of the splenic nerve at 10 shocks per sec for 20 sec also released prostaglandin, as did an intravenous injection of noradrenaline (5 μ g). An α -receptor blocking agent (5 mg phentolamine) was then injected intravenously into the dog and 20 min allowed for α-receptor blockade to develop. When the injection of adrenaline

and the nerve stimulation were repeated, there was now no output of prostaglandin, although there was still some relaxation of the assay organs when the catecholamine reached them. This experiment shows that when the contraction of the spleen is abolished, whether it is induced by adrenaline or by nerve stimulation, the output of prostaglandin is also abolished.

We next attempted to find out whether the prostaglandin was released from activated smooth muscle cells or whether it was present in the stores of blood which were ejected during the initial phases of the contraction. Part

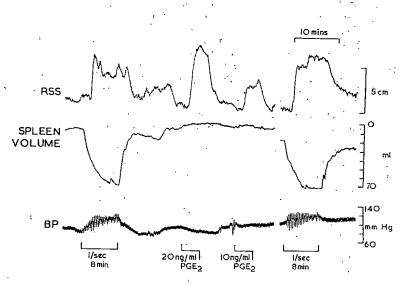

Fig. 6. A rat stomach strip (RSS, top) was superfused with splenic venous blood from a dog. Changes in the spleen volume (middle) and the blood pressure (bottom) were also recorded. The first stimulation (1 shock per sec for 8 min) induced a contraction of the spleen which was maintained, as was the output of prostaglandin. Calibrating infusions of prostaglandin E_a showed that the output was equivalent to about 15 ng/ml. A second stimulation at 1 shock per sec for 8 min gave a similar output. Time, 10 min; vertical scales, 5 cm, change in spleen volume (ml.) and mm mercury.

of an experiment, in which the splenic nerve was stimulated at I shock per sec for a period long enough (8 min) to give a maintained contraction of the spleen, is shown in Fig. 6. During the whole of this period there was an output of prostaglandin equivalent to a concentration of E_2 of about 15 ng/ml. A second stimulation at the same rate 35 min later induced a similar output, suggesting that the output of prostaglandin was associated with active muscle contraction. In many of these experiments, however, there was an output of prostaglandin when the spleen was handled, suggesting that it could occur without an active contraction of the spleen being induced by drugs or by electrical stimulation of the nerve. Experiments in which the spleen is stimulated at different frequencies for long periods of time should help to distinguish between release of prostaglandin from muscle cells and release from the blood stored in the sinusoids. Perfusion of the spleen with an artificial salt solution may also help to elucidate this point.

Our experiments have confirmed that prostaglandins are released into splenic venous blood when the spleen contracts. It is not yet known whether contraction of any smooth muscle will lead to an output of prostaglandin into the venous effluent, although it has been shown that contractions of the rat stomach lead to a release of prostaglandin (see succeeding article). If these potent substances are released from intestinal muscle as well as from the spleen, it seems clear that there is a highly efficient protective mechanism, both in the liver and in the lungs, which will remove almost all the prostaglandin before it reaches the arterial circulation. Thus the prostaglandins are unlikely to be important as circulating hormones, unless they can also be released from the lungs into the pulmonary vein, or unless the mechanism for their removal is disturbed.

We thank the Wellcome Trust and Smith and Nephew Ltd. for fellowships for S. H. F., the Medical Research Council for a grant and Dr J. E. Pike (Upjohn, Kalamazoo) for a gift of prostaglandins. We also thank R. Ginn and R. Flower for technical assistance.

Release of Prostaglandin E_1 from the Rat Stomach

bу A. BENNETT C. A. FRIEDMANN J. R. VANE

Department of Surgery, King's College Hospital Medical School, St Mark's Hospital, and the Department of Pharmacology, Institute of Basic Medical Sciences, Royal College of Surgeons of England,

Prostaglandin is released from the rat stomach during electrical stimulation of nerves in its wall. Sensitivity of gastric muscle to prostaglandins suggests that they have a role in the control of gastric motility.

SEVERAL pharmacologically active substances are released from the isolated stomach during gastric motor activity. Paton and Vane¹ found that acetylcholine appeared in the bathing fluid when gastric nerve endings were stimulated and that the release of 5-hydroxytryptamine (5-HT) and histamine sometimes increased during nerve stimulation or during muscle contraction induced by drugs. It was suggested that these amines are released through mechanical deformation of amine-containing cells rather than through nervous activity per se. Bennett, Bucknell and Dean² found that 5-HT as well as an uncharacterized material were released into the lumen of the rat stomach We now describe further stimulated transmurally. experiments on the release of this material and on its identification as prostaglandin E_1 .

Wistar rats of both sexes were used. They were fed MRC diet B (as modified by Oxo Ltd.). The drugs used were acetylcholine perchlorate, atropine sulphate, bromolysergic acid diethylamide, chymotrypsin, hexamethonium bromide, 5-hydroxytryptamine creatinine sulphate,

(-)hyoscine hydrobromide, mepyramine maleate, methysergide bimaleate, prostaglandins E_1 , E_2 , F_{1a} , F_{2a} and tetrodotoxin. Concentrations of salts are expressed in terms of the base.

Perfusion of Isolated Stomach through its Lumen

The procedure was similar to that previously described^{1,3}. Rats were deprived of food overnight but were allowed drinking water. They were stunned and their throats were cut. The stomach and duodenum were gently removed in one piece and the oesophagus was tied off. A small hole was cut in the fundus and the lumen was irrigated with Krebs solution to remove any stomach contents. A cannula with a platinum wire electrode through its centre was tied into the hole in the fundus so that the stomach could be perfused intraluminally. The preparation was transferred to a bath containing Krebs solution at 37° C gassed with 5 per cent carbon dioxide in oxygen and a second platinum electrode. The duodenum was tied to an outlet cannula

so that the intragastric fluid could be withdrawn at intervals by a syringe. In some experiments the fluid from the stomach was superfused continuously over isolated A perforated polyethylene tube was inserted through a hole in the fundus and out through the duodenum to ensure that the rate of flow of fluid through the stomach was not slowed by occlusion. Each stomach was kept at an intraluminal pressure of 0 cm of water for 10-20 min before the start of the experiment. The pressure was then raised by up to 10 cm water and sometimes there was concurrent transmural or vagal electrical stimulation (2 pulses/sec, 1 msec duration). For transmural stimulation 30-50 V were used; for vagal stimulation, pulses of 5-10 V were passed through two platinum electrodes looped round the oesophagus and the attached vagi. The periods of increased pressure and electrical stimulation were varied according to the type of experiment. In some instances they lasted 1-5 min and alternated with periods of rest at 0 cm water for 5-8 min; in others the stomachs were stimulated continuously at 2-4 cm water until the peristalsis became weak (usually about 30 min).

Pharmacological Assay of the Effluent

The pharmacological activity in the fluid from the lumen of the rat stomach was measured by its contractor effect on the rat stomach strip preparation⁴. This was either suspended in an isolated organ bath in Krebs solution at 37° C gassed with 5 per cent carbon dioxide in oxygen, or superfused directly by the effluent from the stomach at 9–12 ml./min in an apparatus similar to that described for blood-bathed organs. Other rat tissues and rabbit duodenum were sometimes used as well. The responses of the tissues were recorded on a kymograph by isotonic or auxotonic frontal writing levers (magnification, 8–16). The initial load on the tissues was 0-5–1-5 g.

Release of Active Substances

Samples of perfusion (a) Whole isolated stomach. fluid from the lumen of the non-stimulated rat stomach contracted the rat fundus strip prepara-Except on one occasion when spontaneous peristalsis occurred, methysergide or bromolysergic acid diethylamide $(2 \times 10^{-7} \text{ g/ml.})$ almost or completely abolished the contractor effect of the effluent obtained at intragastric pressures of 2-4 cm water (five experiments). Thus, at low pressure, 5-HT was chiefly released. At higher intragastric pressures (10 cm water, two experiments) additional activity which was not antagonized by methysergide appeared in the effluent. During transmural or vagal stimulation at any pressure, activity appeared in the effluent which contracted the rat stomach strip in the presence of methysergide (2 × 10⁻⁷ g/ml.). Fig. 1 demonstrates that only 5-HT was detected in the effluent from the lumen of a non-stimulated rat stomach at an intragastric pressure of 2 cm water, whereas additional activity, not blocked by methysergide, was detected after transmural stimulation. The concentration of this activity declined when stimulation was stopped, but increased again when stimulation was resumed (see later).

(b) Strips of isolated stomach. Strips of rat fundus or of rat gastric body and antrum were cut as described by Vane⁴. One end of the strip was fixed and the other was attached to a short lever so that the tissue could be stretched by the addition of weights. The strips were superfused with Krebs solution at 37° C and the superfusing fluid was then passed in turn over two rat fundus strips. The effect of 5-HT on the lower strip was prevented by the infusion of methysergide into the bathing fluid to give a final concentration of 2×10^{-7} g/ml. When the strips of antrum and body were stretched by weights (4–20 g tension) both of the superfused test strips contracted (four experiments). The strip superfused by methysergide contracted less in relation to the other, suggesting that 5-HT and at least one other substance were

released. No increase in activity in the superfusion fluid was detected when strips of fundus were stretched (4–12 g tension, two experiments).

(c) Release in vivo. Rats which had been deprived of food overnight were either anaesthetized with pentobarbitone (50 mg/kg injected intraperitoneally; four experiments) or were decerebrated under temporary ether anaesthesia (two experiments). The oesophagus and vagi were tied approximately 1 cm above the stomach. Krebs solution at 37° C was passed into the stomach through a tube tied into the fundus and was removed at intervals through a tube tied into the duodenum. Two platinum electrodes were looped round the oesophagus near to the stomach and the vagi were stimulated at 2 pulses/sec (1 msec duration and 10 V) for periods of 5 min. Peristalsis was poor in the rats anaesthetized with pentobarbitone. This was probably the result of the anaesthetic because pentobarbitone (4.3×10^{-6} g/ml.; two experiments) greatly reduced peristalsis caused by vagal stimulation in vitro. Peristalsis was greater in the decerebrate rats, and the fluid from inside the stomach contained uncharacterized material similar to that obtained in vitro. Release of this material was therefore not the result of an artefact caused by isolating the stomach.

Identification of the Active Substance

(a) Pharmacological. As already indicated, the unidentified material was not 5-HT, for its effect on the rat fundus strip preparation was not blocked

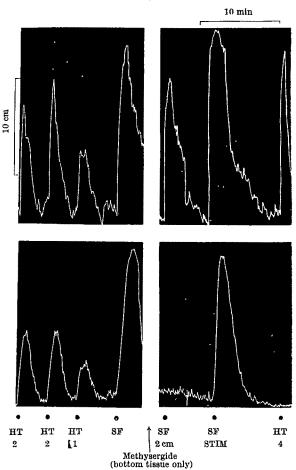

Fig. 1. Two rat fundus strips (top and bottom traces) superfused with the same stream of Krebs solution or with the effluent from a rat stomach perfused intraluminally at 2 cm of water pressure. 5-HT (HT, doses in ng) and the effluent from the non-stimulated stomach (SF) contracted both strips; methysergide (10-7 g/ml., bottom tissue only) prevented these effects. The fluid from the transmurally stimulated stomach (2 pulses/sec, I msec and 50 V for I min; SF STIM) contracted the strips even in the presence of methysergide, showing that another substance was also present.

by methysergide or bromolysergic acid diethylamide. It was not acetylcholine or histamine because its effect was unaltered by hyoscine or mepyramine $(2\times 10^{-7} \text{ g/ml.})$. The substance was not a peptide such as gastrin, bradykinin, vasopressin, oxytocin or substance P because the activity of the effluent was unaltered by incubation with chymotrypsin (10^{-4} g/ml.) for 30 min at pH 8). The substance had no effect on the rat uterus or on the circular or longitudinal muscle of the rat gastric body or antrum, but the rat duodenum, ileum and colon and the rabbit duodenum responded with small contractions. The contraction induced in the rat duodenum further distinguished the substance from bradykinin which causes a relaxation.

(b) Solubility. The Krebs solution containing the unidentified material was shaken with ether. The substance was extracted with ether when the aqueous phase was acid but not when it was neutral or alkaline. This suggested that the substance was an acidic lipid, such as has been extracted from human stomach^{8,9}, and the following procedure was therefore adopted. The ether was first shaken with an aqueous solution of sodium metabisulphate to remove peroxides, and was then washed five times with distilled water. The effluent from the stomach was acidified to pH 2-3 with normal hydrochloric acid and extracted three times with ether, leaving basic substances such as 5-HT in the aqueous phase. The ether extracts were combined and evaporated to dryness at not more than 30° C under a stream of nitrogen. In other experiments, the stomach wall was extracted after cutting the tissue into small pieces with scissors and grinding with distilled water in a Potter-Elvehjem glass homogenizer. resultant suspension was then acidified and extracted in the way described for the effluent. The residue obtained when the ether was evaporated was shaken with 1 ml. of Krebs solution and assayed for contractor activity on the rat stomach strip preparation. The amount of activity recovered from the ether extracts was 26-48 per cent of the total present in the aqueous extracts. Similar incomplete extraction and recovery occurred with pure prostaglandin E_1 .

(c) Spectrophotometry. Because of the relatively large amounts of material required for this technique, the effluents from many stimulated rat stomachs were extracted (eight to twenty-eight in different experiments). The ether extract was dried with anhydrous sodium sulphate and then evaporated under vacuum in the presence of 0.5 g of potassium bromide ('Pronalys', May and Baker). The residue was made into a disk and examined in a Unicam SP 100 spectrophotometer. Pure samples of prostaglandin E_1 and prostaglandin F_{1a} were pulverized with potassium bromide before fusion into disks.

Table 1. INFRARED ABSORPTION DATA FROM THE C=0 STRETCHING REGION

Substance	Frequency (cm ⁻¹) carboxyl	Frequency (cm ⁻¹) carbonyl	Absorbance carboxyl/ absorbance carbonyl
PGE_1	1,710	1,736	0.78
Extract	1,710	1,730	1.06
$PGF_{1\alpha}$	1,695		-

The uncharacterized substance resembles $\mathrm{PG}E_1$ but not $\mathrm{PG}F_{1\alpha}$. The higher proportion of carboxyl absorbance in the extract compared with that of $\mathrm{PG}E_1$ suggests that more than one substance is present.

The infrared spectrum (Table 1, three experiments) in the C=O stretching region showed that both carbonyl and carboxyl groups were present in the extracted material. The wavelengths of these absorptions corresponded to the carbonyl and carboxyl absorptions in prostaglandin E_1 . The higher proportion of carboxyl absorbance in the extracted material (last column, Table 1) compared with that of prostaglandin E_1 suggests that more than one substance is present. If the excess carboxyl absorbance were due entirely to prostaglandin F_{1a} , this compound would comprise about 15 per cent of the total absorbing material in the extract.

(d) Chromatography. In four experiments the material extracted from the effluents of four to eight stimulated

stomachs or the extract from the ground stomach wall was dissolved in 50 per cent methanol. It was chromatographed using the AII system of Gréen and Samuelsson¹⁰ on thin layer plates of silica gel G (Merck) containing 3 per cent of silver nitrate. Pure samples of prostaglandin E_1 , E_2 , F_{1a} and F_{2a} were treated similarly and chromatographed concurrently. Centimetre bands of the plates were then extracted with 1 ml. of 50 per cent chloroform in methanol. After separation from solid matter, the solvent was evaporated at a temperature below 30° C and the residue was shaken with 1 ml. of Krebs solution for biological assay.

The material obtained from effluent or from the stomach wall was detected on the rat stomach strip at the same R_F (0·79) as pure prostaglandin E_1 (Fig. 2). It was thereby differentiated from PGE_2 , PGF_{1a} and PGF_{2a} which had different R_F values. Thus prostaglandin E_1 was present in the stomach wall and was liberated into the gastric lumen during electrical stimulation.

(e) Parallel pharmacological assays. The results from infrared spectroscopy suggested that some F prostaglandin might be present, whereas only E_1 was detected on the rat stomach strip. This preparation is, however, relatively insensitive to F prostaglandins. Parallel assays of ether extracts of stomach wall were therefore performed using both the rabbit duodenum (which is more sensitive to F than E compounds¹¹) and the rat stomach strip. Compared with E_1 the extracts were

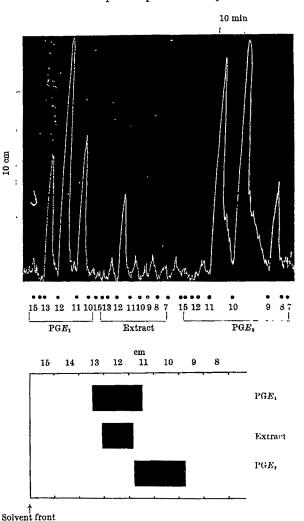

Fig. 2. Parallel chromatograms of rat stomach prostaglandin, PGE_1 and PGE_2 run with the AII solvent system of Gréen and Samuelsson¹6 on silica gel G containing 3 per cent silver nitrate. Consecutive 1 cm bands (as indicated by numbers) were extracted and tested on a rat fundus strip (top). The estimated positions on the chromatogram (bottom) confirm that rat stomach contains PGE_1 .

more potent on the rabbit duodenum than on the rat fundus. The same dose of E_1 plus 10-20 per cent of F_{2a} was as effective as the extract on the rabbit intestine. Thus in addition to E_1 there appeared to be a little F prostaglandin in the stomach wall. Recently, Wolfe, Coceani and Pace-Asciak¹² reported that rat stomach contains prostaglandins (chiefly E_2 and F_{2a}) which are released from the serosal surface during electrical stimulation. Because the only E prostaglandin we found was E_1 , the type of prostaglandin may vary with the strain of rat.

Release of Prostaglandin from Stomach Wall

Effluents and aqueous homogenates of stomach were assayed for prostaglandin on the rat fundus strip treated with methysergide, hyoscine and mepyramine (all at 2×10^{-7} g/ml.). In thirteen experiments the aqueous extracts of stomach contained activity equivalent to $0.35-7~\mu g~E_1/g$ of moist tissue (mean $3.2, S.E. \pm 0.63$). In two experiments the amount in the mucosa was 10.5 and 19·4 μg/g which was four to six times higher than that in the muscle. The release into the effluent in seven experiments during 3 or 5 min periods of stimulation varied from 3-35 ng E_1/\min (mean 11.8, $S.E. \pm 3.8$) of stimulation, and in four experiments 5-25 per cent of the total activity was liberated during stimulation for approximately 30 min. The release of active material into the stomach lumen during periods of 3 or 5 min at 4 cm water pressure either with or without electrical stimulation was determined by assay on the rat fundus treated with methysergide, hyoscine and mepyramine (all at 2×10^{-7} g/ml.). Each period of raised pressure was alternated with a period of rest at a pressure of 0 cm water. Changes in the release of prostaglandin caused by cessation of stimulation or by hexamethonium or tetrodotoxin in the bathing fluid were measured in each sample as changes in the degree of contraction of the assay preparation and not in actual amounts of prostaglandin. In each experiment, when stimulation was stopped the release of active material declined by approximately 25-75 per cent compared with the preceding stimulation period. The amount increased when stimulation was resumed (Fig. 3).

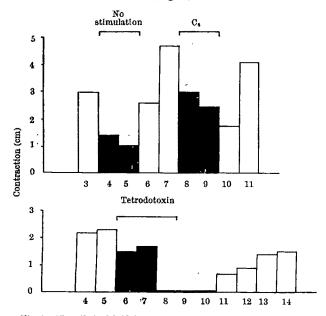

Fig. 3. The effect of fluid from two perfused rat stomachs (intragastric pressure 4 cm of water) on a rat fundus strip blocked with methysergide, hyoscine and mepyramine (all 2×10^{-7} g/ml.). The white columns are the contractions caused by one fifth of the fluid obtained during transmural stimulation for 3 min. The black columns are responses to fluid from the non-stimulated stomach or from the stomach stimulated in the presence of hexamethonium (C_s ; 2×10^{-8} g/ml., top trace) or tetrodotoxin (10^{-7} g/ml. bottom trace). Output of activity falls when stimulation is stopped or when hexamethonium or tetrodotoxin is present and increases again when the drugs are washed out of the bath.

Hexamethonium $(2 \times 10^{-5} \text{ g/ml.})$ added to the bath fluid almost abolished muscular activity in response to electrical stimulation and the stomach became dilated. In each of six experiments the output of prostaglandin fell by 20-60 per cent (average 39 per cent) compared with one or with the mean of the two previous periods without hexamethonium (Fig. 3) but increased again when the drug was washed out and peristalsis had returned. Although the effect of hexamethonium on peristalsis was almost immediate, the output of prostaglandin into the lumen fell only gradually (Fig. 3), as after stopping stimulation.

Tetrodotoxin (10-7 g/ml.) added to the bath fluid nearly abolished the motor response to stimulation. The reduction in the release of prostaglandin ranged from 0-30 per cent in the first 5 min stimulation period after the addition of tetrodotoxin (average 22 per cent; four experiments), but the reduction was 60-100 per cent (average 86 per cent) in the third period while tetrodotoxin was in the bath fluid (Fig. 3). Antagonism of muscle responses therefore preceded the reduction in the release of prostaglandin into the lumen. Output increased again with the return of peristalsis when tetrodotoxin was washed out.

These results show that prostaglandin is released from the rat stomach when nerves in its wall are stimulated. A similar occurrence has been found in the cat spleen (ref. 13 and the preceding article by Ferreira and Vane). Prostaglandin release from the stomach declines when stimulation is stopped or when the nerves are blocked with It has not yet been established whether the prostaglandin comes from nerve, muscle or from mucosa: although both hexamethonium and tetrodotoxin reduce or abolish the excitation of postganglionic nerves, they also prevent muscle contraction induced by electrical stimulation. Prostaglandin-like activity, however, was released from strips of gastric body and antrum stretched by weights, suggesting that it can be liberated by simple distortion of cells.

The greater release of prostaglandin into the lumen of the stimulated stomach compared with the release from the serosal surface12 indicates that the liberation of prostaglandin from the mucosa is greater than from the muscle. This corresponds with the finding that the amount extractable from the mucosa is higher than from muscle and from many other tissues 14. Prostaglandin E_1 and E_2 contract the rat fundus in low concentrations. Their actions on human gastric muscle are more complex because circular muscle is inhibited and some longitudinal muscle is contracted. The sensitivity of gastric muscle to prostaglandins, coupled with their presence in the stomach wall, suggest the possibility that they have a role in the control of gastric motility.

We thank Dr J. E. Pike for samples of prostaglandins, Professor A. H. Beckett and Mr G. McDonough for obtaining the infrared spectra and K. G. Eley for technical assistance. The work by one of us (C. A. F.) was supported by a grant from the Medical Research Council.

LETTERS TO THE EDITOR

ASTRONOMY

Re-examination of the Source Counts for the 3C Revised Catalogue

On the basis of optical identifications by Veron¹ and Wyndham², the 254 extragalactic sources of the 3CRevised Catalogue³ have been divided into the following classes: radio galaxies (RG), quasi-stellar sources (QSS) empty fields (E) and unidentified (?). Log $N-\log S$ curves for all the 254 extragalactic sources, for the RG + RG? (certain and possible), for the QSS+QSS? and for the QSS+QSS? + E + E? +?, have been derived 1,4 , with exponents of -1.85 ± 0.05 , -1.55 \pm 0.05, -2.2 ± 0.1 and -2.2 (no quoted error), respectively. The conclusion was then drawn that the $-2.2 \pm$ 0.1 exponent for the quasars indicated an evolutionary effect which was not shown by the radio galaxies with an exponent of -1.55 ± 0.05 . Furthermore, that the quasars plus the empty fields and the unidentified fields showed the same exponent as the quasars alone was taken as an indication that the empty fields and unidentified fields were quasars.

Because of the importance attached by cosmologists to the number-flux curves for various classes of radio source, a re-examination of the data from the optical identifications of the 3C Revised Catalogue has been undertaken.

In a number-flux analysis of this type, it is important that the individual exponents should be determined in a reliable manner and that good estimates should be obtained for the uncertainties in the exponents. Only in this way can reliable conclusions be drawn from the available data. Although the estimation procedure used by Veron^{1,4} is not stated, his published log N-log S plots indicate that he has fitted theoretical N-S integral curves of the form

$$N(>S) = KS^{-\beta} \tag{1}$$

to the experimentally observed numbers greater than chosen flux levels.

Such a procedure is not directly applicable because the usual fitting methods require that the numbers at each flux level should be statistically independent of each other, otherwise these methods are not applicable. This particular objection to the fitting of integral data was the reason for this re-examination of the published 3C Revised Catalogue identifications.

In the experimental determination of an integral spectrum (that is, the number of sources greater than chosen flux levels) those sources greater than the largest level are included in every other level, those at the next highest are included in all but one, and so on. The result is that most of the sources are counted many times. Because of the large numbers at the lower flux levels, there is the illusion that the range of exponents fitting the data is small. Also, as the numbers of sources are propagated from level to level, neither the numbers at each level nor the uncertainty in these numbers are independent.

The lack of independence of nearby points also affects the estimate of the reliability of the fitted N-S curve. Direct application of a chi-squared test for goodness of fit in the integral spectrum results in an over-estimate of the number of degrees of freedom and consequently in an over-estimate of the reliability of the fit. The propagation of numbers from level to level smooths out any fluctuations within the levels, which is of particular importance when examining any N-S data for a change in exponent.

The exponent, deduced from the fitting to integral data, is thus not necessarily a reliable estimate, and, furthermore, the apparent uncertainty in the exponent is usually somewhat under-estimated. These failings are serious when both the value of the estimated exponent and the reliability of this estimate are to be used to differentiate between various physical theories.

In order to derive a reliable estimate of the exponent in the number-flux curve, it thus seems preferable to fit the differential spectrum rather than the integral spectrum to the experimental results. In this way, the numbers in each flux interval are independent, allowing an application of the usual fitting methods.

The differential form corresponding to equation (1) is

$$N(S)dS = kS^{-a}dS \tag{2}$$

where $\alpha = \beta + 1$. The problem is to estimate k and α given the observed numbers M_i in the various flux intervals. In this respect, the method of maximum likelihood is particularly useful. This approach to the estimation of parameters from experimental data was developed by R. A. Fisher⁵, based on the work of Thomas Bayes, and yields an estimate with a number of important properties⁶.

In order to estimate k and α it is necessary to maximize the likelihood of k and α , given the observed counts M_i in each ith flux interval. This reduces to maximizing the product over all values of i of Poissonian terms of the form

$$[E_i^{Mi} \exp(-E_i)]/(M_i!) \tag{3}$$

where E_i is the expected number in the *i*th interval and is given by

$$E_i = \int_i k S^{-a} dS \tag{4}$$

It is usually more convenient to maximize the logarithm of this product as a function of k and α .

This yields an estimate k^* for k of

$$k^* = \frac{\sum M_i}{\int S^{-\alpha} dS}$$
 (5)

where the integration extends over the range of S covered by the data. The estimate α^* of α is given by that value of α which maximizes the expression

$$\log k^* \sum_{i} M_i + \sum_{i} \log \left\{ \int_{i} S^{-\alpha} dS \right\}$$
 (6)

where the integral is carried out over each ith flux interval. This expression is evaluated numerically.

Notice that if instead of the Poissonian form of expression (3) a normal distribution has been assumed, then expression (6) reduces to the usual least squares equation. Thus least squares fitting in this case is applicable only in the sense that the normal distribution function is an approximation of the Poissonian distribution. In particular, when the numbers in each interval are small, as in the present case, the maximum likelihood estimate is preferable to the least squares estimate.

For the 3C Revised Catalogue, expression (6) was evaluated for $\alpha=2(0\cdot01)4$, determining k^* for each α from equation (5). The most probable estimates of α for the four source classes analysed by Veron are given in Table 1. together with their uncertainties. These uncertainties correspond to those values of α where the expression (6) has dropped by one half from the maximum value. Because the distribution of the likelihood estimate is asymptotically normal, this corresponds to the one

Table	1	
Source class	Previous exponent	Present exponent
All extragalactic	$2 \cdot 85 \pm 0 \cdot 05$	$2.79 \begin{array}{l} +0.12 \\ -0.11 \end{array}$
Radio galaxies RG+RG?	$2\!\cdot\!55\pm0\!\cdot\!05$	$2.58 \begin{array}{l} +0.14 \\ -0.13 \end{array}$
Quasars plus empty fields plus unidentified fields QSS+QSS?+E+E?+?	3·2 (No quoted error)	$8.17 \begin{array}{l} +0.21 \\ -0.21 \end{array}$
Quasars Q85+Q88?	3.2 ± 0.1	$3.00 \begin{array}{l} -0.30 \\ -0.27 \end{array}$

Table 2						
Source class	Present	exponent				
Radio galaxies RG plus empty fields +	+RG? E+E?	2.73	+0·14 -0·13			
Ĉertain radio galaxies	$\mathbf{R}\mathbf{G}$	2.26	+0·13 -0·13			
Certain quasars	QSS	2.56	+0.27 -0.25			
Empty fields	E+E?	3.50	+0.46 -0.48			

standard deviation points of the normal distribution. Column 2 lists the exponents and their errors given previously1,4. Furthermore, Table 2 shows the same analysis applied to a number of other classifications. For comparison, both the present and previous exponents are given as differential exponents.

From Table 1 it can be seen that the present results differ somewhat from those in column 2. In the first place the uncertainty associated with each exponent is considerably larger than the previous value, as is to be expected. Furthermore, the present exponents for each category are not always the same as the previous values.

Regarding the interpretation of the data, the difference between the exponents for the QSS+QSS? and the RG+RG? is now no longer well established, because of the increased uncertainties. The latter value of

$$2.58^{f +0.14}_{f -0.13}$$

is well within twice the uncertainty of the QSS+QSS? value of

$$3.00^{+0.30}_{-0.27}$$

Again from Table 1 it can be seen that the only statistically established difference in exponents is between the radio galaxies (RG+RG?) and the quasars plus empty fields (QSS + QSS? + E + E? +?). The exponents for the quasars and the quasars plus empty fields are no longer the same, and so the arguments classifying the empty fields with the quasars are now not nearly as strong, particularly as the empty fields themselves have an exponent of 3.50 from Table 2. In particular, if the empty fields are classified as radio galaxies, then this classification yields an exponent of 2.73 from Table 2. Both this exponent and that for the quasars (QSS+QSS?) alone are then entirely consistent with the overall exponent of

$$2.79^{+0.12}_{-0.11}$$

Table 2 also shows the effects of the doubtful identifications on the exponents. In all cases, as with the empty fields, they are responsible for a considerable steepening of the counts in each classification; 2.56 to 3.00 for the inclusion of the doubtful quasars and 2.26 to 2.58 for the doubtful galaxies.

It is clear then that no definite interpretation regarding the cosmological significance of the difference between exponents can be drawn from the present 3C Revised Catalogue identifications. In the first place, the difference between the exponents of the quasars and the radio galaxies given in Table 1 is not statistically significant. In the second place, the statistical uncertainties quoted in Table 1 are not a real indication of the actual uncertainties. These are due to the numbers of doubtful identifications, and to the assignment of the empty fields, as well as the statistical uncertainties. In this respect, it seems that there are at present insufficient identification data for the 3C Revised Catalogue to derive any definite conclusions regarding differences between the N-S curves for radio galaxies and quasi-stellar sources. Before any firm conclusions can be drawn, (1) the uncertain identifications should be confirmed, and (2) the empty fields should be further investigated in order to determine with which classification they should be grouped.

At this point it should be noted that the arguments refer only to the differentiation between source groups

on the basis of their number flux curves, and not to the determination of any cosmological model from the observed number flux exponents. This is a separate problem, for it has been assumed in the analysis given here that the radio source flux measurements are exact. This is not the case, for it is known that the errors in the fluxes, particularly at the lower flux levels, are by no means negligible. Moreover, I have shown (unpublished results) that the measured flux values are biased towards an over-estimation of the flux. Once again this bias is greatest at the lower flux levels.

I have carried out a preliminary investigation of the effects of this over-estimate for the extragalactic sources in the 3C Revised Catalogue (unpublished results). The results indicate that the counts corrected for the bias are in good agreement with a differential exponent of 2.5 and therefore the overall counts do not seem to reflect any cosmological effects.

I thank Dr Cyril Hazard for his criticism of the manuscript.

Pre-main-sequence Evolution

In is several years since the first discovery of stellar clusters which appeared to be so young that a number of stars in them were still in the process of contracting onto the main sequence¹⁻⁴. The first theoretical model covering the evolution of stars, on the assumption that their self gravitational energy is the only energy source available, was produced by Henyey, LeLevier and Levée. The results of these computations have been used to produce a theoretical Hertzsprung-Russell diagram for young stellar clusters^{6,7}. In this theory, the evolution of the stars is governed by the equations

$$L = R^2 T^4 \tag{1}$$

$$L\mathrm{d}\tau = -\frac{M^2 \,\mathrm{d}R}{R^2} \tag{2}$$

$$L = M^{\alpha}/R^{\beta} \tag{3}$$

where L, R, T and M denote the luminosity, radius, effective temperature and mass, respectively, all in solar units, and in which T denotes the age in units of the Helmholtz-Kelvin contraction time. α and β are constants with approximate values given by Huang⁶ as $\alpha = 5.4$ and $\beta = 0.79$.

A type of evolution governed by simple equations such as these is mathematically convenient, for it makes it possible to evaluate the mass, radius and age of a star on the basis of the observed luminosity and temperature. Unfortunately, however, it does not correspond with the observed HR diagrams. A large discrepancy between the age of the cluster predicted by this model and the age as deduced from the main sequence turn-off point was pointed out by Huangs, while Williams showed that there is also a discrepancy between the theoretical and observational distribution of stars. The reason for the breakdown

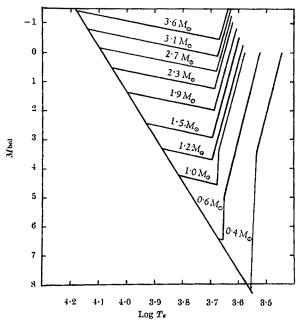

Fig. 1. The evolutionary tracks given by equations (4) and (5) for the stellar masses used by Hayashi².

of these theoretical models was given by Hayashi⁹, who showed that contracting stars would in general possess a convective zone. Consequently, there exists a locus in the HR diagram for every mass, to the right of which no quasi-static solutions can exist. Hayashi therefore proposed a model in which the stars evolve along this locus until it intersects the track of Henyey et al.5 after which they evolve along that track. (He used the values $\alpha = 4.5$, β=0.5, corresponding to an unmodified Kramer opacity for the evolutionary tracks of Henyey et al.) In this way Hayashi produced evolutionary tracks for specified masses and, using these, constructed constant time loci which are in agreement with the observational data. Similar physical models^{10,11} support this argument, and there now seems little doubt that such a model gives essentially a correct description of stellar evolution before the main sequence.

By the very nature of the model proposed, however, it is not possible to represent the evolution by a simple set

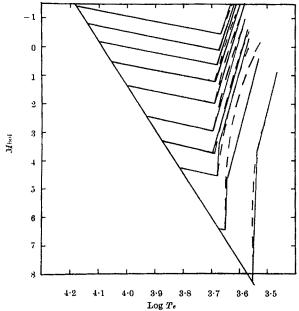

Fig. 2. The evolutionary tracks given by equations (4) and (5) (solid lines) compared with Hayashi's tracks (broken lines), which are superimposed.

		Tal	ole 1		
(M_{\odot})	Log (age)	Log (age) Hayashi	Mass	Log (age)	Log (age) Hayashi
3·6 3·1 2·7	4·65 4·90	4·7 4·9	1·5 1·2	5.95 6.20	6·3
2·3 1·9	5·10 5·30 5·60	5·1 5·4 5·7	0.6 0.4	6·57 7·26 7·80	6·6 7·3 7·7

of equations. Equations (1) and (2) remain valid but equation (3) does not. This means that fresh calculations have to be performed for each stellar mass, which is particularly inconvenient in any discussion of stellar clusters. For this reason we propose an approximation to the Hayashi evolutionary track which can be represented by simple equations. The part of the Hayashi track which differs from that of Henyey et al. is represented by two intersecting straight lines, given by

$$0.21 \log L = 0.46 \log M - 3.16 \log T - \frac{0.195}{1 + 1.36 \log M}$$
 (4)

for high luminosity and changing to

$$0.05 \log L = 2.16 \log M - 3.8 \log T - \frac{0.323}{1 + 30 \log M}$$
 (5)

at the intersection of the two lines. This locus changes to that of Henyey et al. where the two tracks join.

The evolutionary tracks given by equations (4) and (5). for the stellar masses used by Hayashi, are shown in Fig. 1. The tracks of Henyey et al. and the main sequence have been taken from Hayashi's paper. Fig. 2 shows the same evolutionary tracks, but with Hayashi's tracks superimposed, the Hayashi tracks being the broken lines. The discrepancy between the two sets of tracks is very small.

Using equations (1) and (2), it is easily seen that equation (4) corresponds to replacing equation (3) by the

$$L = \frac{M^{\alpha}}{R^{\beta}} 10^{-\frac{0.195}{1 + 1.36 \log M}} \text{ with } \alpha = 0.46 \text{ and } \beta = -1.58$$

Equation (5) requires replacing equation (3) by
$$L = \frac{M^{\alpha}}{R^{\beta}} 10^{-\frac{0.323}{1+30 \log M}} \text{ this time with } \alpha = 2.16$$
 and $\beta = -1.9$

The evolutionary tracks we have proposed can therefore be represented in a form mathematically similar to equation (1) to (3) and calculations can be carried out for this stage of evolution.

For most purposes, the equations can be simplified further. In general, the two lines we have proposed do not cross in a region which is of interest as can be seen from Fig. 1. The evolution is thus governed by one or other of these lines. A good approximation is obtained by taking equation (4) for masses greater than 0.6 Mo and equation (5) for the other masses.

Before these equations can be regarded as a fair approximation to Hayashi's results, the time taken to evolve to the intersection with the track of Henyey et al. must correspond in the two models. It is easy to demonstrate, using the equations given here, that the time taken to evolve to the stage when the luminosity is L_0 and the temperature is T_0 is

$$\tau_0 = \frac{M^2 T_0^2}{(1-\beta) L_0^{3/2}} \tag{6}$$

Taking L_0 and T_0 to refer to the values at the point of intersection with the track of Henyey et al., we find the evolution times (in years) as shown in the second column of Table 1, one HK unit being taken as 107.2 yr. In the third column the corresponding time found by Hayashi is given. Agreement between the two sets of values is again very good.

There are no major differences between the evolution given by our equations and that described by the mathematically more complex evolution of Havashi. In evolutionary work where extreme accuracy is not required, it may therefore be advantageous to use this simple model.

One of us, A. W. C., would like to thank the Science Research Council for a research studentship during the tenure of which this work was carried out.

PLANETARY SCIENCE

Upper Atmosphere Density in 1966-67: the Dominance of a Semi-annual Variation at Heights near 200 km

ANALYSES of the changes in satellite orbits have established that the principal variations in upper atmosphere density at heights between 180 km and 1,000 km are attributable to solar activity and differences between day and night. A further effect, usually smaller, is the semiannual variation, with maximum densities in April and October and minima in January and July. These results are embodied in the Cospar International Reference Atmosphere and other models of the upper atmosphere.

Solar activity has been greater and more variable during 1967 than during 1966, and might have been expected to exercise a dominating influence over upperatmosphere density during 1967. This expectation has not been fulfilled, however, particularly at heights near 200 km. A recent analysis of the orbit of the satellite Secor 6 (1966-51B) has yielded 154 values of air density at a height of 191 km at dates between June 14, 1966, and July 5, 1967. These results, which will be reported in detail elsewhere, show that solar activity, as represented by the radiation energy at a wavelength of 10.7 cm, did not exercise appreciable influence over the air density. Nearly all the nineteen large geomagnetic disturbances occurring during the life of the satellite were accompanied by sharp increases in air density for a few days; but, when these disturbed days are eliminated, the remaining variations in density are apparently quite unrelated to the wide variations in the 10.7 cm radiation energy, which shows a strong 27-day recurrence over much of the satellite's life in orbit.

The values of air density obtained from the orbit of Secor 6 at a height of 191 km are shown in Fig. 1, after removing geomagnetically disturbed days and making small corrections for the long-term increase in solar activity and for day-to-night variations in density.

(Values between August 23 and September 17, 1966, are regarded as doubtful, because of lack of data and also because several points at times of geomagnetic disturbance had to be removed.) The chief feature of Fig. 1 is a semiannual variation, with maxima of about 5.0 × 10-10 kg/m³ in October 1966 and April 1967, and minima (excluding the doubtful September values) in July 1966 and January 1967 of about 3.7 and 3.2×10^{-16} kg/m³, respectively. These values are averages over about 30 days, rather than extreme maxima or minima. This semi-annual variation, with the maximum density exceeding the minimum by a factor of 1.45, has been in many respects the most important variation in upper-atmosphere density during 1967 at heights near 200 km, and has significantly affected the accuracy of satellite lifetime estimates.

The semi-annual variation in air density, found from the orbit of Echo 2 by Cook and Scott² at a height of 1,130 km at dates up to January 1967, is almost identical in form to the left-hand half of Fig. 1, although the numerical values of density are lower by a factor of more than 105 This confirms that the density at 1,130 km height. variations apparent in Fig. 1 are dependent on date.

The apparent failure of solar activity to influence upper-atmosphere density at heights near 200 km, except through the short-lived solar outbursts which give rise to geomagnetic storms, suggests that the radiation responsible for controlling upper-atmosphere density during the declining years of the last sunspot cycle may not be as strong during the rising part of the current cycle.

Differences of Composition among Australian Iron Meteorites

THE discovery of iron meteorite fragments with the structure of medium octahedrites in the neighbourhood of the Wolf Creek meteorite crater compounded a curiosity. The Boxhole and Henbury craters were already known to be associated with meteoritic debris which has the structure of medium octahedrites and although such structures are relatively common among iron meteorites-Hey's2 catalogue shows them to represent 36 per cent of all classified irons—coincidence of structures has caused speculation that two or more of these cratering events

were produced by fragments of the same meteoroid.

The Boxhole and Henbury craters lie about 300 km apart along the N.E.-S.W. line in central Australia (Northern Territory). Wolf Creek is located in western Australia about 850 km N.W. of this area, and thus the three objects do not lie along an arc of the Earth's surface. Although such distances are small by Australian standards, they are much greater than the linear dimensions of any known meteoritic strewn field, as recently discussed by

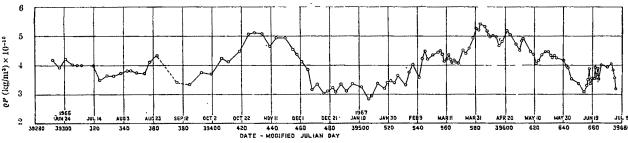

Fig. 1. Values of density, or at a height of 191 km, averaged between day and night, with geomagnetic storms excluded.

No. 5118 DECEMBER 2, 1967 Vol. 216

Where should Books be Kept?

CONTINUING uncertainty about the future of the British Museum does at least have the advantage of provoking thought about the functions of national libraries, and by now, no doubt, Mr Patrick Gordon Walker's friends are probably saying that this is what he intended, all along, when he brought the planning of the museum trustees abruptly to a halt four weeks ago. However that may be, Mr Gordon Walker has done a good deal to make up for his heavy-handedness by his decision to have Dr F. S. Dainton as the chairman of the committee which is to re-examine the difficult issues which have tended to be glossed over in the past twenty years. For one thing, Dr Dainton is a scientist. For another, he has played an active part, in the past few years, in fostering experiment in information retrieval. The gibe that the literature is too important to be left to the librarians is, of course, unjust, for librarians have done more than scientists in recent years to ensure that the literature of scholarship shall be managed in an orderly fashion, but it will be a great boon if the planning of new national libraries in Britain can now be seen to be in the charge of one who is sympathetic to the problems of the librarians but who is also demonstrably a user as well.

But what should the Dainton committee push for? And how can it hope to complete so huge a task in less than a year, as the Secretary of State for Education and Science has promised? The difficulty is that the planning of a national central library system should properly depend on much more information about the detailed needs of potential users than is at present available. There is, for example, the question of whether a central reference library in London can adequately cater for the needs of people living and working in other British cities. And what should be the relationship between university libraries and the rest of the community? How feasible is it to separate science libraries from other kinds of libraries, especially now that there is a boom in bridge subjects such as economics and architecture? And even if this is feasible, can it be sensible? There are also questions to be answered about the character of library readership. What value is there in bibliographies, produced by machine or otherwise? What criteria should be adopted for distinguishing between material which is readily accessible and material which is more remotely stored? What policies should libraries follow in the collection of foreign-language material? Who or what should foot the bills?

Dr Dainton's only comfort in this forbidding list of questions is that urgency and the pressure of work may

serve enormously to clarify the mind of his committee. This, so it is said, is the effect of impending execution. And it should not be hard to establish a few simple principles which should quickly help to create a framework within which a new national library service could The starting point should be a forthright recognition that a national library system is so urgent that the link between the British Museum and the library now on the same premises, however valuable, is comparatively unimportant. The two functions need to be divorced. It is also plain that if there is to be a Central Reference Library worthy of the name, it should span all branches of scholarship, science and otherwise. It follows that the Dainton committee should work for a single building to house everything on some easily accessible site in central London. There is also a case for asking that the result should be integrated administratively-not physically-with the central lending libraries. One of the absurdities of the present arrangements is that the overflow from the British Museum library cannot be used by the National Lending Library for Science and Technology, for example. But there is an even stronger case for bringing university libraries more firmly within the national system. It would be better—and cheaper—for everyone if the principle were formally acknowledged that the academic libraries are also regional libraries of great importance.

There are also technical matters which cry out for a firm and, if necessary, authoritarian decision. The time, for example, has come to deprive librarians of the right to develop independent cataloguing systems in the misguided notion that they thus serve the interests of their readers. No cataloguing system can be ideal, but the advantages of a common system override the virtues of any one of them, especially now that computers have arrived in libraries. Indeed, the advantages of uniformity are now so great that it may even be worthwhile to establish international computer facilities for the cataloguing of material and the compilation of bibliographies. The Library of Congress and the British Museum have in the recent past done much to stimulate each other. Has the time now come when they should merge? And should there now be arrangements for pooling the collections of nearby countries in Europe? British libraries are notoriously deficient in material from France, Germany and Eastern Europe. And, finally, there are the computers. Some means must be found for fitting these new machines into the library system in such a way as to leave people with some sense of freedom. Dr Dainton will have a busy year ahead of him.

ARTS AND SCIENCE

Arts v. Science

A Collection of Essays. Edited by Alan S. C. Ross. Pp. x+158. (London: Methuen and Co., Ltd., 1967.) 30s. net.

THE publication of the Dainton Report is likely to underline once again the damage done to our whole educational system, and now particularly to science education, by the premature choice and excessive degree of specialization in the arts and science sides of our sixth forms. It is depressing evidence of our lack of any effective machinery of change that in spite of almost universal agreement, clutches of conferences, reams of reports and at least two elaborately considered proposals for reform (one from the Vice-Chancellors, the other from the Schools Council) the structure of specialization into arts and science sides, basically recruited at the age of fourteen, has remained unchanged during the last ten years. Only some of the pupils have, in defiance both of Crowther and of one of Mr Lunt's theses in this book, demonstrated their resistance to the dichotomy in spite of all the contrary pressures. Combined A level courses in arts and science have been one of the two growth points in the sixth form over the last decade: and pure science courses, the most heavily specialized option, have declined.

The issue is one of the most important in the whole field of education, if only because of its by-product, the shortage of scientists and technologists entering the universities. Not unnaturally many eminent men have therefore contributed to the debate and Professor Ross has done us a service, not only in his introduction, which is one of the best sections of the book, but in preserving these occasional essays and giving them wider distribution. That, at least, is what he seems to have done; for the diversity of the contributions makes it seem unlikely that, except for the Birmingham group, they were commissioned for this publication, or that the authors were chosen on any particular plan or writing to any common brief.

Books of this kind have one advantage, which is that each author usually contributes because he has had something valuable to say, though the balance of value may be very unevenly distributed. In a book of only 157 pages, for instance, it seems hardly worth devoting twelve to Mr Lunt's analysis of the views of so small and unrepresentative a sample as the sixth form of one direct grant grammar school. Another variation seems to be in the date at which the essays were written. Mr Henn's, for example, clearly pre-dates the realization of the sixth form swing away from science; Mr Lunt's shows the first signs of alarm in quoting the shortfall of science entrants in 1964. It is left to Professor Roy Pascal, in one of the best essays in the book, to accept categorically the need for more science entrants and to suggest once more the remedy which has seemed obvious for the last ten years "that the number of applicants might be increased if it could be brought about that, by taking science, students do not have to abandon all arts subjects".

Mr Kenneth Richmond writes well and makes the useful point that the results of his own rather more extensive cross-cultural tests gave no support either to the Crowther or the Snow thesis, but revealed what most psychologists would have expected, that students of very high IQ were less and not more likely to be "subject-minded" in

Crowther's exclusive sense, or limited to one side or other of the Snow line.

Two of the essays develop unusual interests peripheral to the main discussion. Professor Whitfield discusses the Italian futurists of the 1920s in relation to the distinction between humanism and scientific humanism: Professor Hilton of Cornell discusses power politics in American universities in reference to a general thesis that, at the level of scholarly research, there is no essential difference between the disciplines of science, mathematics and history or literature, except that the application of scientific method to the "arts" subjects is much more difficult and therefore as yet less advanced.

TEACHING PHYSICS

Nuffield Foundation Science Teaching Project

Physics. Guide to Experiments I. Pp. xvi+248. 17s. 6d. Teachers Guide I. Pp. xiv+306. 15s. Teachers Guide II. Pp. x+156. 12s. 6d. Teachers Guide III. Pp. viii+356. 15s. Teachers Guide IV. Pp. viii+404. 17s. 6d. Questions Book I. Pp. vi+86. 5s. Questions Book II. Pp. vi+72. 5s. Questions Book III. Pp. vi+134. 5s. Questions Book IV. Pp. vi+114. 5s. (London: Longmans, Green and Co., Ltd.; Harmondsworth, Middx.: Penguin Books. Ltd., 1967. Published for the Nuffield Foundation.)

THE Nuffield Foundation Science Teaching Projects have now for some years made increasing impact on teaching within the schools and on thought about science teaching over a much wider area. The books under review form a substantial part of the material prepared for teaching up to the Ordinary level of GCE in physics. They represent a degree of coherent and well discussed planning in the subject far beyond anything which has previously been attempted. For anybody not in course of operating Nuffield Physics, it is the teachers guides which bring out most clearly the spirit and intention of the operation, and few who have grown up with the difficulties and weaknesses of teaching in the subject will not admire and agree with a great deal of what is set out there.
